The study of these nitrogen balance figures, with varying calories and percentages of protein, presuming both to be nutritionally adequate under normal conditions, have convinced us that the optimum nutritional requirement for the sick individual should contain the full metabolic caloric requirements within which 25 or 30 per cent of the calories should be derived from protein. The optimum daily requirement of protein in health has been established at approximately 1 gram per kilogram of body weight (70 grams for a 154-pound man). In sickness, this requirement may need to be doubled. Certainly, it should not be decreased.

Experiments cited in the medical literature have shown quite convincingly that tissues heal more slowly and inadequately if protein requirements are not maintained. Nitrogen balance studies have indicated that sick individuals and almost all postoperative patients obtain very rapidly a negative nitrogen balance. This may be due both to an inadequate protein or caloric intake and to the excess destruction of protein incident to the illness. We have observed that when the fever increases, the nitrogen balance decreases, as illustrated by comparing periods XV and XVI.

It is almost routine in many hospitals to prescribe no food for the first twenty-four or forty-eight postoperative hours. On the first postoperative day (twenty-four hours after operation) the patient is allowed clear liquids, in which there are no calories and no grams of protein. On the second postoperative day a general liquid diet provides 903 calories and 24 grams of protein. On the third postoperative day a soft diet provides 1,510 calories and 41 grams of protein. On the fifth postoperative day a regular diet provides 2,259 calories and 70 grams of proteins. Presuming that the patient eats all that is offered, he receives inadequate protein throughout his entire hospital stay. These hospital diets provide approximately 10 per cent of the calories from protein. This is only a few points higher than the lowest protein diet that a dietician was able to devise when we asked for such for one very co-operative young lady in the interest of these studies. I presume that we might have tried Crisco and corn syrup.

By the time the patient has reached a full diet stage on the usual postoperative routine, he has been so severely starved of protein that it may require ten or fourteen days before he again regains his nutritional balance. It is no wonder that a patient feels so exhausted and lacks energy and has lost weight when he leaves the hospital.

Comments and Conclusions

We believe that the use of morphine preoperatively is entirely superfluous, and that its postoperative use has become much too routine. There are so many undesirable features of morphine which can be eliminated only if the use of morphine is discontinued. Satisfactory analgesia can be obtained in most instances with the use of intravenous alcohol and non-narcotic analgesics.

No significantly undesirable features have been produced with the intravenous use of glucose, amino acids and alcohol.

Routine hospital diets are shamefully deficient in protein.

On the basis of our nitrogen balance studies, we believe that nitrogen equilibrium can be obtained on a relatively low caloric intake, if adequate nitrogen is given. It is difficult, however, to maintain a strong positive nitrogen balance, unless adequate calories are provided to cover the metabolic needs. When this is done, a surplus of nitrogen can be retained. This is necessary for healing processes, whenever the need arises from surgical or medical diseases.

If adequate nutrition (protein, carbohydrate and calories) cannot be eaten by the convalescent individual, these should be supplemented with intravenous feedings.

We believe, as we shall eventually endeavor to prove, that patients who have been placed on this regime have a feeling of well-being within twenty-four hours after operation and present a lower incidence of morbidity while in the hospital, because they have not been deprived of adequate nutrition for any period of time.

Must we continue to keep our patients in a state of constant semistarvation when we already know from numerous experiments and clinical observation that it is not beneficial to the healing and feeling of well-being in our patients?

Discussion

DR. L. H. FOWLER: Dr. Rice, have you noticed any problem in the nursing care of these patients given alcohol? I have heard that they have been discouraged because of the difficulties in nursing care.

DR. CARL RICE: I have noticed problems with nurses. The nurses don't like to measure anything, but that might be our fault, since we require the nurse to measure and save urine output, to weigh daily caloric intake, and to do numerous other minor chores.

DR. D. MACKINNON: I would like to ask if the admission and discharge weights are the same—if there is any correlation between nitrogen balance and weights?

DR. CARL RICE: We found a correlation in a large series. We have kept daily weight records of patients who receive this medication and have observed a gain in weight during the hospital stay. We observed a 10-

pound gain in weight for one individual who received nothing but intravenous feeding for over three weeks.

Dr. Arthur Zierold: I believe such a paper as this deserves an extended discussion as it represents a tremendous amount of work and is one of the few scholarly attacks upon what has been a clinical problem heretofore. I most heartily agree with the basic ideas Dr. Rice has advanced and have attempted to follow them myself.

When Key's work on starvation is published we shall have a considerable fund of information which will aid us in measuring the effect of nitrogen balance. The well-nourished individual will probably tolerate a longer period than we believe at this time without a critical loss of his tissue protein. That is one thing. Another thing is that we have difficulty in determining a base line. We have no good means of determining the state of the individual's tissue protein unless we go to the extent of taking a specimen, digesting it, analyzing it and determining exactly what his state of nutrition is, because plasma protein tends to be constant at rest. We have no good base line and Dr. Rice had to accept an arbitrary figure and take this as normal without any exact measurement. We all know that most of our patients get along in spite of the nutrition we have forced upon them and that is in some small way evidence that the average individual will tolerate starvation for a considerable time without arriving at a critical level. In the average case, it is probable that it will not be necessary to use parenteral means to maintain positive nitrogen balance. While it is highly desirable that the individual maintain positive nitrogen balance throughout his period of stay in the hospital, again let me say that the majority of the individuals who have not suffered exhaustive disease, who have not had considerable weight loss (excluding infants as well as the elderly), are individuals in the middle decades of life and are in a good state of nutrition. They will not need parenteral nutrition unless there is protracted starvation. For some time at the Minneapolis General Hospital we have fed exhausted patients beef plasma by mouth and found that a good means of measuring nitrogen balance, and I am inclined at the present time to attempt to maintain that by feeding amino acids and other proteins by mouth and by tube if possible. My patients are fed that after operation, sometimes the day of operation, and you expect them to return to a normal diet at once. They have no liquid diet but a solid diet, except the patients who have operations on the stomach or upper intestinal tract. Except in a very few instances, it is not necessary to starve these patients more than four days and most of the patients will tolerate that.

Use of glucose has been mentioned. There is a phase of glucose action which I don't believe has been noted commonly, and that is its effect on smooth muscle. If you will take a piece of intestine in the laboratory and put that on a nerve muscle and saturate that in an isotonic glucose solution, that muscle will relax at once. That is experimental evidence of its effect on smooth muscle. Clinical evidence can be demonstrated in your own children. They will eat sweets, become satiated and the musculature will relax. Another illustration is in operations on the gastrointestinal tract. You will notice during operation that the peristalsis will become much more noticeable, and if you will give that individual a little concentrated glucose, you will notice the gastrointestinal musculature will relax and become quiet. I mention this because I believe that there is evidence to indicate that we precipitate ileus by repeated and excessive amounts of glucose.

Now it is necessary to use that glucose in the ultization of amino acids. I am very much interested in the use of alcohol because I have been casting around for several years for something to substitute for morphine because it gives rise to what the patient calls "gas pains." I don't like that term. It implies distortion where no distortion exists. It is probably spasm in the morphine half of the morphine compound. I would be delighted if we could use alcohol as a sedative to do away with morphine after operation. There should be very little sedation. Early ambulation and early feeding can dispense with hospital diets of fifty to 100 years ago, as they are certainly not adequate or suited to the surgery we practice today.

Dr. Hamlin Mattson: I would like to ask Dr. Rice if nitrogen balance figures were broken down for early ambulation or prolonged bed rest. Bed rest alone can induce negative nitrogen balance. Was that considered in the study?

Dr. Carl Rice: No. We did not break down the figures as to early ambulation. When giving the patients early feeding, we found it difficult to hold them in bed.

Dr. L. C. Culligan: I would like to ask with reference to cost of supplying patients with 2 to 3 liters of nitrogen with added alcohol. It is my offhand opinion that it would cost $3 or $4 per liter, perhaps up to $5. Am I wrong in that? In other words, it would cost $12 to $15 per day to give the patient 2 to 3 liters of fluid. The use of alcohol in that way is tied up with the utilization of vitamin B in the body. I wonder whether adequate doses of vitamin B and vitamin C are supplied?

Dr. Carl Rice: If the patient feels well in twenty-four hours, the cost is little, and the feeling of well being on the first postoperative day is worth the cost. Vitamins B and C are provided as described in the text of the article. The patient is given intravenous vitamins B and C every day that parenteral feedings are used.

Dr. L. H. Fowler: I would like to ask whether there is any correlation between the amount of alcohol given by mouth and that by vein. Couldn't it be given by mouth as well?

Dr. Carl Rice: Alcohol taken by mouth produces a "hang-over." Whiskey, 84 proof, given by mouth provides 42 per cent alcohol. Intravenously, 95 per cent alcohol is used with aminosal or amigen. After an operation, the gastrointestinal tract is upset already, and it is my impression that the gastrointestinal tract does not take food well for twenty-four hours, so we let patients go without food by mouth and provide them with parenteral calories for the first twenty-four-hour period. In 95 per cent of our patients, that is all they require. After that we put the patients on a full diet. If the patient is not eating the caloric requirement, we give him another bottle intravenously. These studies were made on long-time hospital cases where they couldn't eat and we had to provide them nutrition.

Dr. E. H. Henrikson: If gas pains should persist after benzedrine sulphate intravenously, how long before you should repeat it, and should you use phenobarbital to offset benzedrine?

Dr. Carl Rice: We have repeated benzedrine in about four hours. In most instances, benzedrine gave relief in fifteen minutes to one hour. Benzedrine given intravenously produces a slight rise in blood pressure. It is well to use some sedative after having given benzedrine, in order to counteract the wakeful effect of benzedrine.

Dr. E. Benjamin: Are the alcohol and amino acids available in a commercial preparation?

Dr. Carl Rice: Yes. The glucose and amino acids are available commercially. We obtain alcohol out of the jug from the drug room, using the 95 per cent strength, merely adding it to the commercially prepared amigen or aminosal.

Communications

LABORATORY SERVICE

To The Editor:

In the April (1948) issue of MINNESOTA MEDICINE appears a communication addressed to the Editor from Dr. C. J. Ehrenberg, commenting on the objections of the practicing clinical pathologists to a resolution approved by the House of Delegates of the Minnesota State Medical Association, petitioning the State Board of Health to include routine Rh typing in its laboratory service (see MINNESOTA MEDICINE, 31:81-82, January, 1948).

Dr. Ehrenberg intimates that the State Board of Health Laboratory would be doing only the typing of blood for Rh factor and no more. Experience has clearly shown that such a limit cannot be placed upon the State Board Laboratory, once the practice is sanctioned by the medical profession. Not only would the State Laboratory be willing and anxious to extend its facilities to include all phases of the complex Rh work, in which it is fully capable, but, I am afraid, the practicing physician would practically force it to render services connected with the Rh typing, such as the sensitization test, the Anti-Rh titre determination, as well as testing of blood of the husbands and children, for no other reason than that they are done free and thus "cushion" the cost of medical care.

Syphilis is a public health problem only in a limited sense. Personally, I believe, the medical profession with the existing private diagnostic facilities at its disposal, can and should control the spread of the disease. Free Wassermann testing was introduced as a war measure during World War I. In some states it was continued to benefit only the indigent. This was soon proved unworkable, since the doctors would have the test performed free, regardless of the patient's financial ability (and in some instances the doctors themselves appear to pocket the "fees" for the tests). Today, all state laboratories are doing, not only the serologic tests for syphilis, but in some instances, giving expert consultation service in diagnosis and treatment. The same trend would follow if we should let the State Board Laboratory take charge of the mere routine Rh test for married women.

It is well known that cancer diagnosis is the next target of the State Board of Health. Several states have already inaugurated this service free to all physicians.

Dr. Ehrenberg states, "Controversy as to the principle involved becomes trivial." The clinical pathologists, as practicing physicians, are fighting for the principle, which, to them and I hope to all thinking practitioners of medicine, is paramount in the issue. Once it is compromised, any and all phases of medical practice, be it clinical, diagnostic, or therapeutic, may and can be interpreted, as one chooses, as a public health or human problem "which transcends limited interest of the individual."

In the final disposal of the resolution, let the doctors decide on the merit of the principle involved which should govern their own practice, and not on the expediency which is another wedge into the gradually widening path leading to socialized medicine.

KANO IKEDA, M.D.

April 26, 1948.

BLUE CROSS-BLUE SHIELD NATIONAL ASSOCIATION

To the Editor:

In regard to the proposed Blue Cross-Blue Shield national organization which was discussed at the Blue Shield-Blue Cross conference in Los Angeles on March 30, the Minnesota Hospital Service Association had present its executive director and Minnesota Medical Service Inc., its executive director. Mr. F. Manley Brist, counsel for Minnesota Medical Service Inc., also attended and Dr. Adson from Rochester attended as a member of the Associated Medical Care Plans. Action taken regarding this national association was as follows:

"Following the motion passed at the joint session of the Blue Cross and Blue Shield Plans to the effect that there be established an effective and democratic association of Blue Cross and Blue Shield Plans to serve local Plans in the achievement of their fullest usefulness, your Committee has again considered the entire problem of a more effective association for facilitating and strengthening the work of the Blue Cross and Blue Shield Commissions.

"1. It is our recommendation to the Blue Cross and Blue Shield Commissions and to the Conferences of Blue Cross and Blue Shield Plans that an association be created, empowered to do any and all things necessary to serve the interest of the public and the Plans in providing prepayment facilities so that we may stimulate and put into effect a health program that will be to the benefit of the people of this country.

"2. We recommend that the present Commission structures be not disturbed at this time, and that a new *association* be formed which will supplement the work of the two Commissions.

"3. We recommend to the Blue Cross and Blue Shield Plans and to their respective Commissions that the two Commissions be directed to organize such an *association* at the earliest possible time and submit a written plan of operation to the respective Plans for approval within a six months' period.

"4. It is the unanimous judgment of your Committee that it would be desirable for the Commissions to consider the following basis of representation: The Board of Governors of the *Association* shall be composed of one Blue Cross Director, one Blue Cross Trustee, one Blue Shield Director and one Blue Shield Trustee elected from each of the twelve districts; there shall also be four representatives of the American Hospital Association and four representatives of the American Medical Association on the Board of Governors, the Board of Governors to serve one-third, one year, one-third, two years, and one-third, three years. It is also our judgment that in view of the fact that the Board of Governors will consist of fifty-six persons, a strong executive committee should be chosen to administer the work between meetings. We recommend that the

(Continued on Page 586)

"... a considerable reservoir of unsuspected and unreported amebiasis has been brought back to the United States...."[1]

Urging clinicians and roentgenologists to be on the alert for signs of this disease, Wilbur and Camp[2] note the frequency with which the radiologist finds unsuspected lesions, ultimately diagnosed as amebiasis.

Diodoquin . . . high-iodine-containing amebacide . . . "is a valuable addition to the therapeutic remedies available for the treatment of this insidious and intractable disease."[3]

Diodoquin may be employed in acute or latent forms of amebiasis. Relatively nontoxic, well tolerated, Diodoquin does not produce unpleasant purgation and may be administered over prolonged periods.

BLUE CROSS—BLUE SHIELD

(Continued from Page 584)

executive committee consist of the chief executive officer of the *association* and the officers of the *association,* who shall be elected annually by the governing board. In addition, the governing board shall elect annually additionl members of the executive committee up to a total of eleven. The members so elected must include one of the members of the Board of Governors representing the American Hospital Association and one of the members of the Board of Governors representing the American Medical Association and, exclusive of the chief executive officer and the American Hospital Association and American Medical Association representatives, consist of two Blue Cross Trustees, two Blue Cross Directors, two Blue Shield Trustees and two Blue Shield Directors. Not more than three members of the executive committee shall come from any one district.

"Among the purposes set forth for this association, as outlined above, there shall be included the organization of a national service agency or plan on a non-profit basis, to provide prepaid hospital and medical care, which will supplement coverage of Local Plans where desirable and which will provide coverage where no Blue Cross or Blue Shield Plan is available to national employers.

"Your Committee is in agreement that every effort must be made to maintain and protect individual Plan autonomy. The Committee believes that one of the greatest hazards to be faced in the establishment of our national association with a subsidiary non-profit Insurance Corporation is that the latter corporation might syphon off local business. Your Committee therefore recommends that the Insurance Corporation transmit all funds collected less reasonable operating expenses (to be determined by the Board of Governors) to the local Blue Cross or Blue Shield Plans. Each Plan would then provide all benefits to subscribers under its regular contract, and also administer the coverage (referred to above) made available through the Insurance Corporation. In this way, all local relations and contracts with hospitals and doctors would be maintained even though variations in benefits for national employers might be in effect. Under the proposal as submitted, each Plan will retain its own subscribers in national accounts. Each Plan will issue its own subscription agreements and deal with the subscribers enrolled through national employers as though no intermediary were employed except for payment of subscription rates."

Until the national association can be formulated and approved or disapproved by each individual Blue Cross Plan board of trustees and Blue Shield board of directors, the following action was taken in regard to Dr. Paul R. Hawley by the Joint Executive Committee of the Blue Cross and Blue Shield Commissions:

"Present.—J. Douglas Colman, Louis H. Pink, F. P. G. Lattner, Richard M. Jones, L. Howard Schriver, M.D., Barrett E. Nelson, M.D., Howard Hassard, Jay C. Ketchum, F. L. Feierabend, M.D., Frank E. Smith, and Paul R. Hawley, M.D.

"The meeting convened at 4:40 p.m., March 26, 1948, Mr. J. Douglas Colman serving as chairman of the meeting, having been chosen by lot. The immediate matters of joint interest to the Blue Cross and Blue Shield Commissions attendant upon Dr. Hawley's assumption of duties as chief executive officer were discussed at length by the group. It was agreed that the following recommendations would be made to the Blue Cross and Blue Shield Commissions by their respective executive committees in attendance at this meeting.

"1. That three members each from the executive committees of the Blue Cross Commission and Blue Shield Commission serve as the Joint Executive Committee to administer the joint undertakings of the two Commissions.

"2. Dr. Hawley will report to and be solely responsible to the Joint Executive Committee on all matters of joint concern to the Blue Cross and Blue Shield Commissions. He will be directly responsible to the Blue Cross and Blue Shield Commissions, respectively, only on such matters as in his judgment are of sole concern to either of these bodies.

"3. The directors of the Blue Cross and Blue Shield Commissions, respectively, shall be administratively responsible to Dr. Hawley and through him to the Blue Cross and Blue Shield Commissions, respectively.

"4. That the annual meeting of both Blue Cross and Blue Shield Plans should be held jointly at a date in the Fall of 1948, to be selected by the Joint Executive Committee.

"5. That the Joint Executive Committee should select its chairman, determine its own procedures, and that its chairman should alternate between representatives of Blue Cross and Blue Shield Plans semi-annually, and that the chairman first be selected by the Joint Executive Committee following the annual meeting of Blue Cross and Blue Shield Plans in the Fall of 1948.

"6. That the principle be established that the areas included within the respective districts of the Blue Shield Plans and the Blue Cross Plans should be identical.

"The matter of sharing of joint expenses incurred in the future joint activities undertaken by the Blue Cross and Blue Shield Commissions was discussed and it was agreed that this should be referred to the joint meeting of the two Commissions, with the understanding that whatever division of expenses was agreed upon should apply to all joint activities and that there should not be any selective division of expenses applying to specific joint activities. The representatives of the Blue Shield Commission suggested that some more equitable sharing of expenses than the tentative 80-20 suggestion be considered. The representatives of the Blue Cross Commission made it clear that any pro ration of these expenses would be entirely acceptable to them.

"The matter of the sharing of the expenses of the current Joint Conference of Plans was discussed and it was agreed that this should be referred to the joint meeting of the Commissions for their decision.

"The matter of suitable office quarters for Dr. Hawley and the staffs of the two Commissions was discussed at length. It was agreed to recommend to each Commission that the entire staffs of both Commissions be quartered at a single location and this location be other than that now occupied by the staff of either Commission."

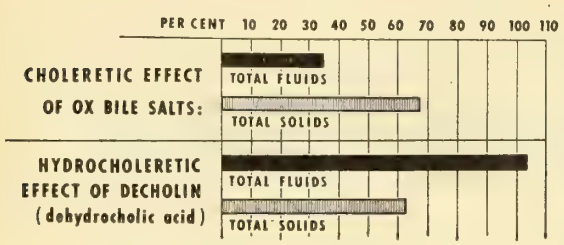
Pioneers In

MEDICAL ACOUSTIC INSTRUMENTS

Your position of trust in the community cannot be jeopardized. Your needs are great, your requirements exacting. Only the finest instruments are worthy of your trust.

For over a decade the Maico Company has been designing, engineering, testing and producing the finest medical acoustic instruments to meet the exacting demands of the medical profession.

- Precision Maico audiometers give the doctor hearing test facilities of great precision. 90% of all audiometers sold are Maico.
- Maico's **Stethetron,** the electronic stethescope, opens a new era in auscultation. New ease of diagnosis is possible through the miracle of electronics.
- The Maico **Atomeer,** the miniature hearing instrument that is bringing better hearing to many thousands, is designed and built to the same high standards as the most complicated medical acoustic instrument.



You can select any of the precision electronic instruments made by Maico with complete confidence that they will serve you and your patients well. The finest of materials, the skilled research and engineering behind each Maico product is your assurance of trustworthiness and quality.

DECHOLIN HYDROCHOLERESIS Encourages Biliary Tract Drainage

● **Percentage Increase in Composition and Quantity of Bile Flow**

Ivy, A. C., et al: Am. J. Dig. Dis. 7:333 (Aug.) 1940.

HYDROCHOLERESIS—

an increased production of thin liver bile—is a desirable approach to therapy of non-obstructive biliary tract disturbances.

DECHOLIN—

by producing an increased flow of bile—washes stagnant, infected bile from the intrahepatic and extrahepatic biliary passages, removing pus-laden material and discouraging the ascent of infection.

HOW SUPPLIED:

Decholin in 3¾ *gr. tablets. Packages of* 25, 100, 500 *and* 1000.

Decholin

WOMAN'S AUXILIARY

Nicollet-Le Sueur

The Auxiliary to the Nicollet-Le Sueur Medical Society held a tea Wednesday, April 14, at Rundstrom Hall on the Gustavus Adolphus campus, St. Peter. Dr. Robert N. Barr, Minneapolis, guest speaker, presented the subject of "Cancer." The meeting was open to the public.

At the same time high school and college girls were invited to hear a talk given by several county nurses, the college nurse and the public school nurse on "Shortage of Nurses and Need for Recruitment of Girls for Nursing."

Ramsey County

In observance of National Health Week, the Auxiliary to the Ramsey County Medical Society was host to representatives of clubs and civic organizations at a guest day meeting, Wednesday, April 14, 1948, in the medical library, Lowry Medical Arts Building.

Dr. Stewart C. Thomson, associate professor in the University of Minnesota medical school, spoke on "Looking Backward and Forward in Health." Motion pictures of rehabilitation work at Veterans' hospital among spastic children were shown.

Organizations which had exhibits for the meeting included the Minnesota Public Health association, Dr. E. A. Meyerding, executive secretary; Minnesota Society for the Prevention of Blindness, Mrs. Dorothy Hamilton, executive secretary; American Cancer Society, Inc., Allan Stone, director; School Health, Dr. G. W. Snyder, school physician; Minnesota State Department of Health, William Griffith, director; Minnesota Heart Association, Thomas Morrow, executive secretary, and enrollment committee of the Minnesota Nurses' Association, Mrs. Dolores Colesworthy, chairman.

Mrs. Louis Benepe, auxiliary president, presided at the gathering, which was followed by a tea.

Renville County

The Auxiliary to the Renville County Medical Society met Tuesday evening, April 13, 1948 at the New Clock Cafe at Olivia at 7 P.M. for a steak dinner. No business meeting was held. Members preferred to stay at the joint meeting with the Medical Society to hear Dr. Miller of Minneapolis speak on "Neurosis in General Practice."

Stearns-Benton

The Auxiliary to the Stearns-Benton Medical Society met Friday evening, March 19, 1948 at the home of Mrs. E. N. Milhaupt, St. Cloud. Assistant hostesses were Mrs. E. V. Wetzel and Mrs. J. E. Conway.

Mrs. Julius Buscher and Mrs. T. N. Fleming reported on the State Health meeting recently held in Minneapolis. Mrs. Wm. Friesleben asked for articles for the layette the Auxiliary maintains for needy mothers. Reports

were given by the following chairmen: Mrs. R. N. Jones, Red Cross and Postwar Planning; Mrs. S. J. Raetz, Historian; Mrs. Carl Luckemeyer and Mrs. E. V. Wetzel, Membership, who reported Mrs. Lawrence Kuhlmann of Melrose as their newest member; Mrs. Joseph B. Gaida, Publicity. Mrs. T. W. Hovorka, treasurer, reported on the financial status of the Auxiliary.

Mrs. Jones introduced the speaker of the evening, Miss Martha Van Brussels, who gave an instructive and interesting talk on "What St. Cloud is Doing for Its Crippled and Handicapped Children." She divided her talk into four points: (1) History of the project, (2) Educational progress, (3) Social Aspect, (4) Advantages of Children attending Summer Camp, financed through the sale of Easter Seals.

Nineteen members answered roll call. During the coffee hour Mrs. Buscher poured.

Washington County

The Auxiliary to the Washington County Medical Society met Tuesday April 13, 1948 at Stillwater. The Dutch treat luncheon was held at the Grand Cafe. Guest speakers, both from Minneapolis, were Mrs. Harold Wahlquist, president-elect of the State Medical Auxiliary and Mrs. F. H. K. Schaaf, president of Hennepin County Auxiliary.

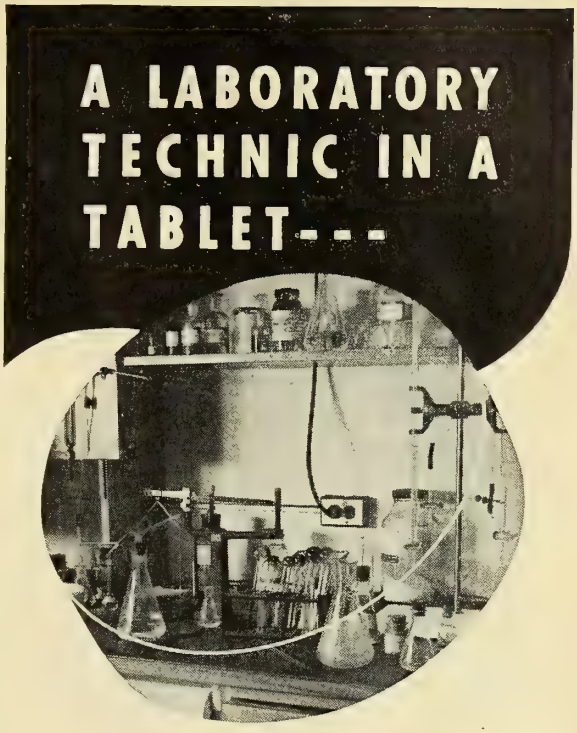
Minnesota Academy of Medicine

Meeting of January 14, 1948

The Annual President's Meeting of the Minnesota Academy of Medicine was held at the Town & Country Club on Wednesday evening, January 14, 1948. Dinner was served at 7 o'clock, and the meeting was called to order at 8:15 by the President, Dr. T. A. Peppard.

There were fifty-five members and four guests present.

The following Past Presidents of the Academy attended: Drs. Henry L. Ulrich, John E. Hynes, J. C. Litzenberg, R. T. La Vake, Carl B. Drake, J. A. Johnson, Martin Nordland, Harry B. Zimmermann, A. G. Schulze, S. E. Sweitzer, and the retiring President, Dr. Ernest M. Hammes.



Dr. Wallace Cole was master of ceremonies and called on Drs. Hynes and Litzenberg for short speeches.

Dr. E. M. Hammes, of Saint Paul, then gave his address as retiring president, on "The Drug Addict," which appears on page 481 of this issue.

The paper was discussed by Drs. Adson, Hastings, and Hammes in closing.

The meeting was adjourned.

A. E. Cardle, *Secretary*

Of General Interest

In Mahnomen, Dr. Kenneth W. Covey and Dr. Kenneth A. Danford moved into newly remodeled offices on March 15.

* * *

Dr. L. M. Evans of Sauk Rapids served as chairman of the cancer fund drive conducted in the village during the month of April.

* * *

A free tuberculosis clinic was held in the county nurse's office in Brainerd on April 10. In charge of the clinic was Dr. A. G. Saunderson.

* * *

In Olivia on March 10, Dr. A. A. Passer spoke on heart disease and the Minnesota Heart Association at a meeting of the local American Legion Auxiliary.

* * *

Dr. J. Emery Frank, Marshall, was elected commander of the Mongeau-Tholen Post of the Veterans of Foreign Wars at a meeting of the organization on March 10.

* * *

At a meeting of the Seventh District Medical Society in Sioux Falls, S. Dak., on March 30, Dr. W. B. Martin of Rochester presented a paper entitled "Physical Medicine in General Practice."

* * *

Participating in a basic science course for army officers at Walter Reed Hospital in Washington, D. C., on March 26 and 27, Dr. W. E. Herrell of Rochester presented a series of lectures on antibiotic agents.

* * *

Dr. K. B. Corbin, Rochester, spoke on "The History and Neurologic Examination in Cerebral Localization" at a meeting of the Department of Neurology of the University of Minnesota Medical School on March 25.

* * *

"The Rh Factor in Pregnancy" was the title of a talk given by Dr. Edward A. Banner, Rochester, at a meeting of the Blue Earth Valley Medical Society at Fairmont on March 25.

* * *

At the dedication of a new science building at Concordia College in Moorhead, Dr. Stanley W. Olson, assistant director of the Mayo Foundation, spoke on "The Application of Basic Sciences to Modern Medicine."

* * *

Dr. Avery De Hart Prangen, Rochester, was elected president of the Minnesota Academy of Ophthalmology and Otolaryngology when the organization met on March 12.

* * *

About the middle of March, Dr. D. H. Garlock of Bemidji went to Philadelphia to attend the graduation of his son, Grant Garlock, who received his doctor of medicine degree from Hahnemann Medical College.

During the last week of March, Dr. S. B. Seitz of Barnesville was in Chicago taking a postgraduate course at the Cook County Hospital Graduate School of Medicine.

* * *

After completing a three-year fellowship at the Mayo Clinic on April 1, Dr. Leonard L. Lovshin moved to Cleveland to become a member of the staff of the Crile Clinic.

* * *

Dr. Hermina Hartig, Minneapolis, discussed the work of the Minneapolis Public School Health Department at the regular monthly meeting of the Deaconess Hospital auxiliary in Minneapolis on March 19.

* * *

A talk on cancer was given by Dr. F. C. Closuit, Aitkin, at a meeting of the Aitkin Lions Club on March 31. Dr. Closuit spoke in the interests of the cancer fund drive which was then getting underway.

* * *

Principal speaker at a meeting of the Jefferson Parent-Teacher Association in Duluth on April 13 was Dr. E. Irvine Parson, Duluth, who presented a health talk.

* * *

In April, Dr. Harry Berge opened offices for the general practice of medicine in Isle. He is located in newly remodeled quarters in the Thorsten Building in that city.

* * *

Among Minnesota physicians attending a meeting of the American College of Surgeons in Minneapolis, March 15 and 16, were Dr. L. H. Rutledge and Dr. A. R. Ellingson, both of Detroit Lakes.

* * *

In St. Louis on March 18, Dr. Robert E. Priest, Minneapolis, spoke at a meeting of the otolaryngology group at Washington University, on the subject, "Tracheotomy in Bulbar Poliomyelitis."

* * *

Assisting in the presentation of a basic science course for army officers at the Army Medical Center in Washington, D. C., during the week of April 5, Dr. W. F. Kvale of Rochester gave a series of lectures on peripheral vascular diseases.

* * *

"Rheumatic Heart Disease" was the topic presented by Dr. A. R. Barnes, Rochester, president of the American Heart Association, when he addressed the members of the Queen City Post of the American Legion Auxiliary on March 23.

* * *

A postgraduate course on physical medicine for the internist, under the sponsorship of the American College

of Physicians, was conducted in Rochester during the week of March 22 to 26. The course was under the direction of Dr. F. H. Krusen of the Mayo Clinic.

* * *

At a meeting of the Medical Society of the County of New York, held in New York City on March 22, Dr. J. R. McDonald, Rochester, presented a paper entitled "The Detection of Pulmonary Neoplasms by the Cytology of Sputum."

* * *

Opening of the Johnson-Haberle Clinic in downtown Thief River Falls was announced on March 11 by Dr. H. C. Johnson and Dr. C. A. Haberle of that city. The clinic occupies fourteen rooms on the first floor of a newly constructed building.

* * *

Dr. Deane W. Benton, formerly of New Ulm, has become associated with the Boyd Clinic in Long Beach, California. He began his duties there on April 15. For the past two years Dr. Benton was associated with Dr. Howard A. Vogel in New Ulm.

* * *

Late in March, Dr. L. B. Kiriluk of Hallock became associated in practice with Dr. J. S. Collins in Wabasha. A graduate of the University of Minnesota Medical School in 1945, Dr. Kiriluk served in the army from April, 1946, to March 10 of this year.

* * *

In Albert Lea on May 1, Dr. E. T. Richlitz became associated in practice with Dr. F. G. Folken. A graduate of Marquette University, Dr. Richlitz has taken post-graduate work at the University of Southern California and has served for five years in the armed forces.

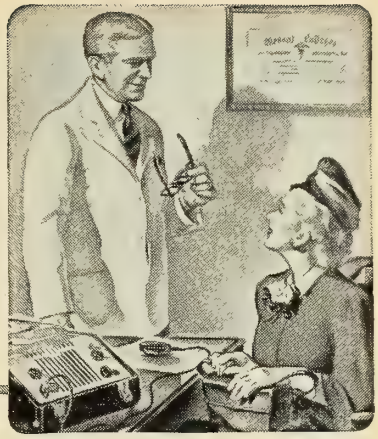
* * *

Dr. Jerome T. Syverton has been appointed professor and head of the Department of Bacteriology and Immunology in the University of Minnesota Medical School, it was announced April 9. He succeeds the late Dr. Robert G. Green.

* * *

While in California attending a conference of the American College of Physicians in San Francisco in April, Dr. and Mrs. Russell Sather, Crookston, visited relatives in Los Angeles, then returned to Crookston on April 26.

* * *



President of the Duluth Heart Association is Dr. Robert L. Nelson, Duluth, who was recently elected to head the organization which will carry out the work of the National Heart Association in northeastern Minnesota.

* * *

In Washington, D. C., on April 8 and 9, Dr. Robert R. Kierland of Rochester participated in the April symposium of the Syphilis Study Section of the United States Public Health Service. He presented a paper entitled "The Treatment of Neurospyhilis with a Combination of Malaria and Penicillin."

* * *

Announcement was made on March 11 that Dr. Robert F. Mears and Dr. Joseph C. Belshe, both of

versity of Minnesota Medical School, Dr. Peterson served his internship at Sacramento County Hospital, Sacramento, California.

* * *

Dr. G. Charles Wilcox, a native of Brainerd, arrived in St. Peter on March 24, one month after his discharge from the army, to become associated in practice with Dr. C. S. Strathern. A graduate of the University of Minnesota Medical School in 1943, Dr. Wilcox interned at Miller Hospital in Saint Paul, then spent two more years there with a residency in surgery. In 1946 he entered the army where he specialized in the treatment of eye, ear, nose and throat diseases.

* * *

Principal speaker at a luncheon in the Saint Paul Athletic Club on April 1, Dr. Owen H. Wangensteen, professor of surgery at the University of Minnesota, launched the American Cancer Society's educational and fund-raising campaign in Saint Paul. Stating that more deaths from cancer can be expected as the age of the population increases, he said that cancer detection centers like the one recently established at the University "remain the promise of the future to people of our own generation."

* * *

More than a half million dollars will be given by United States and Canadian life insurance companies for research in heart disease in 1948. This raises to $1,800,000 the total donated by the Life Insurance Medical Research Fund for this purpose since 1945. Thirty-one hospitals, medical colleges and special research clinics and fourteen individual doctors will share in these donations for research. Approximately $18,900 has been allocated to Dr. Maurice B. Visscher of the University of Minnesota for research on physical factors in cardiovascular function.

* * *

Three lectures were presented by Dr. H. J. Moersch, Rochester, at the twenty-first annual spring graduate course of the Gill Memorial Eye, Ear and Throat Hospital in Roanoke, Virginia, early in April. Titles of the lectures were "Value of Bronchoscopy in the Diagnosis of Pulmonary Disease," "Hiatal Hernia" and "Nebulization in the Treatment of Tracheobronchial Disease." On April 8, at a meeting of the staff of the Medical College of Virginia Hospital, in Richmond, Dr. Moersch spoke on "Treatment of Esophageal Varices by the Injection of a Sclerosing Solution."

* * *

The role of discipline in the emotional development of the child was discussed by Dr. Edward Dyer Anderson, Minneapolis, at an open dinner meeting held by the Duluth Mental Hygiene clinic board in Duluth on March 30. Dr. Anderson, a clinical associate professor of pediatrics at the University of Minnesota, was in general pediatric practice before serving as a captain in the navy in World War II. Since his return to civilian life he has limited his practice to the emotional problems of children and adolescents. He is president-elect of the Hennepin County Medical Society.

Baby-sitters were frowned upon by Dr. Benjamin Spock, Rochester, when he spoke at the Midwestern Conference on Nursery Education in Minneapolis on April 3. Pointing out that babies who are looked after by a different baby-sitter every night may grow up with various anxieties and other serious characteristics, Dr. Spock stated, "At the age when children form their strongest emotional attachments to their parents and need that kind of security, they're being cared for by a string of strangers." Dr. Spock is director of the Rochester child health project.

* * *

A new office building was opened by Dr. A. D. Mattson in St. James on April 5. A graduate of the University of Minnesota Medical School in 1939, Dr. Mattson interned at St. Mary's Hospital in Duluth, then became associated with Dr. C. J. Henry at Milaca for one year. In 1942 he began four years of service in the army, three years of which were spent in China with the 14th Air Force. After his discharge he lived in Madison for a year and was affiliated with the Madison Clinic. While his new building was being constructed at St. James, Dr. Mattson accepted a temporary appointment to the staff of the state hospital at St. Peter.

* * *

A three-day continuation course in cardiovascular diseases was conducted at the Center for Continuation Study at the University of Minnesota on April 15, 16 and 17. Among the lecturers for the course were Dr. George E. Fahr, professor of medicine, who spoke on diagnosis and treatment of acute coronary thrombosis, and Dr. John S. Gillam, medical fellow in obstetrics and gynecology, who described care of the obstetrical patient with heart disease. Other subjects discussed at the conference included rheumatic heart disease in children, recent advances in the use of cardiac drugs, and diagnosis of congenital heart disease.

* * *

An appreciation dinner was given in Wayzata on May 3 for Dr. Thomas J. Devereaux, a practitioner in Wayzata for twenty-seven years.

Waitresses for the dinner, which was attended by 250 friends of the doctor, were young ladies who had been ushered into the world by Dr. Devereaux. Clellan Card, Minneapolis radio personality, acted as master of ceremonies for a program which followed the dinner. Although Dr. Devereaux had given no indication of retiring, the dinner was given for him by local residents who wanted to show their appreciation for his years of service. Date chosen for the occasion was the physician's birthday.

* * *

The annual Duluth Clinic lectures, held at the University of Minnesota on May 11 and 12, were delivered by Dr. Arthur Grollman, professor of experimental medicine at Southwestern University, Dallas, Texas.

On May 11, Dr. Grollman spoke on "Recent Advances in the Pathogenesis and Treatment of Hypertension," and on May 12, his subject was "The Thyroid Gland and Its Disorders." At an informal seminar on May 12,

* * *

Dr. Thomas J. Kenyon has become associated with Dr. John A. Lepak in the practice of internal medicine, with offices at 1065 Lowry Medical Arts Building, Saint Paul.

After graduating from the University of Minnesota Medical School in 1937, Dr. Kenyon obtained a masters degree in pathology and hematology, then served as pathologist at St. Joseph's Hospital in Saint Paul until he entered the army. While in military service he was head of the pathology department of Northington General Hospital at Tuscaloosa, Alabama. For the past year he has had a residency in internal medicine at Ancker Hospital, Saint Paul.

* * *

Thirteen neighborhood immunization clinics were held in Minneapolis during the week of March 29 to April 2. Infants and children of pre-school and elementary school age were given first immunization or booster inoculations against diphtheria. Smallpox vaccinations were also given as needed. Four weeks later the clinics were again held to give the second inoculation in the diphtheria immunization procedure.

The clinics were sponsored by the Minneapolis Health Action Committee and were conducted under the direction of the Minneapolis Health Department. Parents who were financially able were expected to pay 50 cents per child towards the cost of the service.

* * *

Plans to create a medical arts center in Northfield were announced on March 11 by Dr. Stanley T. Kucera of that city. The schedule called for construction to begin early this spring, and it was expected that the building would be ready for occupancy by fall.

Dr. Kucera and Dr. I. F. Seeley, who recently formed a partnership, will occupy the entire first floor of the north wing of the structure. Additional quarters will be available for other professional men, including space for a drug store.

During the middle of March, Dr. Kucera spent a week in New Orleans, taking a postgraduate course in surgery at Tulane University. Shortly after his return to Northfield, he was the principal speaker at a meeting of the Pre-School Mothers Club on March 23, where he discussed "Emergencies and Signs of Communicable Diseases."

* * *

Dr. Viktor O. Wilson, chief of the special services division of the Minnesota Department of Health, resigned his position, effective May 15, to become city health officer in Rochester. He succeeds Dr. F. M. Feldman, who resigned to go to Washington to become director of the central office of co-ordination and analysis of the tuberculosis study section, National Institute of Health, United States Public Health Service.

A graduate of the University of Minnesota Medical

WITH MAY-O-LITE . . .

you never have eyes in the back of your head!

Recently a Minnesotan who works in a large manufacturing plant complained of eye strain. His office desk was arranged so that the windows were at his back, thereby eliminating the extreme light from the southern exposure. However, venetian blinds on the windows reflected in his glasses. Not only was it a strain upon his eyes, but it was bothersome. Quite often he even found himself counting the slats of the blinds. It was as if he had eyes in the back of his head.

The next time his glasses were changed, he had them coated with MAY-O-LITE. Today, he says, "I don't have any more slat trouble."

When objects behind you reflect in your glasses it causes additional eye strain, tends to make you nervous and irritable.

MAY-O-LITE is a scientific method of cutting down annoying surface reflections on your glasses. With MAY-O-LITE, the reflections are reduced from 80 to 95%, eye strain is minimized and lenses become far more resistant to scratches.

MAY-O-LITE Low Reflection Lens Coating is available through your manufacturing and dispensing optician. Write for a descriptive pamphlet and a treated sample of glass, today.

MAY RESEARCH

School in 1931, Dr. Wilson interned at Ancker Hospital, Saint Paul, then studied pediatrics at two Chicago hospitals, engaged in private practice in pediatrics in Minneapolis, served on the staff at Ah-Gwah-Ching Sanatorium, and obtained his M.P.H. degree at Johns Hopkins in 1937. He joined the Minnesota Department of Health in 1937, serving as assistant director of the division of maternal and child health for two years and as director of the division from 1939 to 1946.

* * *

Among physicians attending a three-day continuation course in surgery at the University of Minnesota, April 8, 9 and 10, were Dr. Francis M. McCarten, Stillwater; Dr. F. F. Meyer, Faribault; Dr. Julius E. Haes, Mankato; Dr. W. Howard Parker, Chisholm; Dr. F. H. Baumgartner, Albany; Dr. C. W. Moberg, Detroit Lakes; Dr. William C. Heiam, Cook; Dr. Robert A. Glable, Plainview. Dr. K. L. Stensgaard, Thief River Falls; Dr. James J. Kolars, Dr. Carl W. Rumpf, and Dr. Donald J. Studer, all of Faribault, and Dr. Robert Delmore, Roseau.

Under the direction of Dr. Owen H. Wangensteen, chief of the Department of Surgery of the University Medical School, the course was designed to present newer concepts and developments in preoperative and postoperative care of patients Included in topics discussed were treatment of brain tumors, use of dyes in tumor diagnosis, treatment of burns, early ambulation, and present trends in combined anesthesia.

In discussing brucellosis at a meeting of the American College of Physicians in San Francisco during April, Dr. Wesley W. Spink, professor of medicine at the University of Minnesota, said that there are indications that the disease incidence is increasing both in domestic animals and in human beings. Dr. Spink urged the enactment of strict legislation to require the pastuerization of all animal milk used for human consumption, as a means of reducing the incidence of brucellosis in man.

He stated, however, that since no practical means exist for preventing individuals from contracting the disease by direct contact with infected animals, "the solution of this problem ultimately resides in the elimination of brucellosis from the animals. That," he said "would require the combined support of farmers, livestock producers, veterinarians, packing plant authorities and public health officials." The annual cost of the disease to the cattle industry alone in the United States, Dr. Spink stated, is almost $100,000,000.

HOSPITAL NEWS

Without waiting for Federal grants, Marshall will build its Weiner Memorial Hospital as soon as arrangements can be made, it was reported early in April.

Since Marshall is forty-seventh on the priority list of the state hospital plan, it probably would not be eligible for Federal aid for another two years. The city at present has a fund of $300,000 on hand, partly from a $150,000 bond issue which was approved in

1944, and partly from a presentation made by Ben and Julius Weiner in memory of their father, Louis Weiner.

With the state hospital plan relieving some of the pressure that would be on the proposed Marshall hospital, it has been recommended that a fifty-bed hospital be constructed rather than the eighty-bed one originally planned. Present costs may exceed $8,000 per bed. A fifteen-acre site for the hospital has already been purchased.

* * *

The Long Prairie Commercial Club, after listening to a talk by Dr. M. E. Mosby on Federal aid for hospital construction, decided at its meeting on March 16 to form a hospital committee to investigate the situation and gather information about it. Long Prairie is nineteenth on the priority list of the state hospital plan.

* * *

Though the Moose Lake State Hospital is one of the most modern state mental hospitals in Minnesota, Dr. Henry Hutchinson, superintendent, stated early in April that the hospital is admittedly in need of increased personnel and additional funds to provide better care for the mentally ill.

Dr. Hutchinson said that while the hospital had the advantages of better buildings and perhaps better food service, it would need five ward doctors instead of two, and double the attendant load, to meet the standards approved by medical authorities.

* * *

Mr. Louis W. Hill, Sr., Saint Paul, who died at the Miller Hospital on April 26, 1948, gave $500,000 to the hospital in February of this year for the construction of a new wing, to face College Avenue to the east of the present structure. Mr. Hill had also made previous donations to the institution. He was the son of J. J. Hill, and succeeded him as president of the Great Northern Railroad.

* * *

Beginning May 3, and continuing through May, June and July, Dr. D. A. Dukelow, Director of the Health and Medical Care Division of the Minneapolis Council of Social Agencies, will broadcast a series of health talks entitled "Let's Talk About Health." These broadcasts, under the sponsorship of the Community Chest and Council of Minneapolis and Hennepin County, will be made each Monday at 7:15 p.m. over KUOM.

* * *

At the ninetieth annual meeting of the Lutheran Minnesota Conference held at Center City, on May 6, it was decided to build two additional units to Bethesda Hospital, Saint Paul; a nurses' home at an estimated cost of $750,000, and accommodations for persons suffering from chronic ailments, with an estimated cost of $250,000. It was also decided to construct an addition to Trinity Hospital, Ashland, Wisconsin.

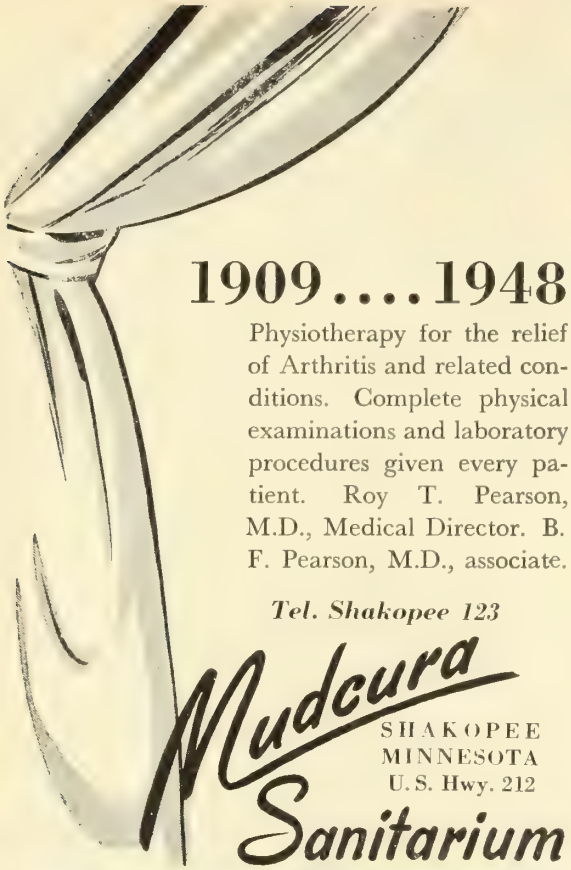
claim on January 15, 1948, there has been little publicity and no official announcement of its inauguration. On April 12 and 13, 1948, such a program was carried out with Dr. Paul R. Hawley, the newly appointed chief executive officer of the Blue Cross and the Blue Shield Commissions, launching the Plan.

Prior to accepting the post of chief executive officer of Blue Cross and Blue Shield, Dr. Hawley was a physician in the United States Army for thirty years, attaining the rank of Major General, and in World War II was responsible for the medical care of the troops in the European theater. After the war, he accepted the position of Chief Medical Officer of the Veterans Administration under General Omar Bradley. While with the Veterans Administration, he became known for his ability to cut government red tape and get things done, for his determination to "give the veterans the best in American medicine" and his insistance upon the "human touch" in the treatment of patients.

The highlight of the inauguration was the inaugural dinner held in the Grand Ballroom of the Coffman Memorial Union on the campus of the University of Minnesota on the evening of April 13, 1948.



More than 4,000 invitations were sent to persons throughout the state. All doctors, state representatives and senators were invited to attend. Also invited to attend were nurses, newspaper and magazine editors, leaders of industry and labor, leaders in the field of public health both locally and nationally, members of the clergy, Blue Cross and Blue Shield group leaders and all Blue Cross and Blue Shield office personnel.

More than 800 people attended the dinner and heard Dr. Hawley deliver the inaugural address which was broadcast from radio station WTCN at 9:30 p.m. The address was "An American Health Plan Based on the American Principle of Free Choice," after which the following exerpts were taken:

"There isn't any question but in America today we have the best medical care in the world. We have more doctors per capita in this country, and we have better doctors. American doctors are no longer going to Europe for their graduate studies and training. They are taking them right at home. In fact, European medical students are now coming over here—to America—for their final training. And we have more hospitals, more nurses, more x-ray technicians and other skilled health workers in America than any other country. Not only more, but the best trained doctors, the best hospitals, and the most hospital beds per capita than any other country.

"I spent thirty-two years in government service, and I can guarantee that our government is the most extravagant operated today.

"Now the answer to the cost problem, of course, is to split the cost of medical and hospital care over a long period of time. There are several ways of spreading the cost. One way is through compulsory government health insurance, and it is interesting to note that in all the government plans for government control, the word 'compulsory' is used. The government health insurance would mean the compulsory purchase of food, drugs, and other things. The socialization of

medicine would be the first step toward the nationalization of industry. And the nationalization of our health service would destroy the feeling of independence, personal responsibility and security which is so essential to our democratic society. The government has destroyed these virtual values whereever it has encroached upon the framework of individual enterprize and upon the personal responsibility and initiative of the individual person.

"There is only one alternative to compulsory government medicine. That alternative is voluntary medical and hospital care. Now, there are three types of voluntary health care:

"One such type is co-operative. The objection to this type of voluntary insurance is that is provides for no choice of physician and that it is difficult to get first class physicians to serve in a co-operative venture.

"The next type of voluntary insurance is the commercial carrier of insurance. In this type you must be careful to read your contract or policy thoroughly, especially the small print. Only a few reputable and reliable companies are selling health insurance, and there are a lot of little insurance companies putting out health policies and these are the ones of which you must be very careful.

"The third type—the voluntary prepayment plans—the Blue Cross and the Blue Shield Plans. First of all, these are nonprofit Plans and that means they can sell their services cheap. Secondly, they are underwritten by the people themselves and benefits are guaranteed by the hospitals in the cases of hospitalization, and by the doctors in the cases of medical and surgical care. Their contracts are clear, there is no fine print, and they preserve the American principle of free choice of hospital and physician.

"Blue Shield in Minnesota has clear objectives and a clear concept, and its enabling act provides for the free choice of physician. The law under which it operates prevents the practice of medicine as a corporation. Under Blue Shield you do not lose your benefits if you move from one state to another, or from one group to another. Every good citizen should be interested because it helps them to spread medical care to the people who need it. Families with low incomes should be interested because it provides a way for them to get medical care when they need it without jeopardizing them to finance it. Families with adequate, average income should be interested because sudden illnesses are provided for, and sudden illnesses can be expensive and wipe off the budget of the average income family. Industrialists and businessmen should be interested because this Plan, together with Blue Cross, is going to help prevent the nationalization of medicine. The nationalization of medicine, as I said before, is the first step toward the nationalization of all industry and of all free enterprize.

"Blue Cross Hospital Service Plan and the Blue Shield medical/surgical Plan are operated on a purely voluntary basis and provide for hospital expenses and the cost of physicians' services. Under such voluntary movements as these, a feeling of social responsibility and security is fostered among individuals, and this is essential to our democratic principle and society.

"As voluntary nonprofit agencies, Blue Cross and Blue Shield are the most successful media whereby services of our doctors and hospitals can be made available to the people on an economical basis. Each Plan is locally sponsored and locally controlled. Each operation is adjusted to meet local needs and existing facilities for health care. In other words, the Blue Cross and Blue Shield hospital and medical care plans are a part and parcel of our democracy. They represent the 'American Principal of Free Choice.' "

Blue Shield has now been launched in Minnesota and its growth and success is assured.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

DISEASES OF THE NOSE, THROAT AND EAR. William Lincoln Ballenger, M.D., F.A.C.S., Late Professor, School of Medicine, University of Illinois, Chicago; and Howard Charles Ballenger, M.D., F.A.C.S., Associate Professor and Acting Chairman of the Department of Otolaryngology, Northwestern University School of Medicine, Chicago; Surgeon, Department of Otolaryngology, Evanston Hospital, Evanston, Illinois; Assisted by John Jacob Ballenger, B.S., M.D., Research Fellow in Otolaryngology, Northwestern University School of Medicine, Chicago. 993 pages. Illus. Price, $12.50. Philadelphia: Lea & Febiger, 1947.

This revised edition is a highly recommendable textbook. There are not many others which cover the field of otolaryngology so thoroughly; any recent progress made in this field is included, adequately discussed and excellently illustrated. This is particularly true in regard to the subjects—rhinoplasty, radiation therapy and fenestration operation in otosclerosis. It is a most useful reference book for the postgraduate and practicing otolaryngologist.

JOHN J. HOCHFILZER, M.D.

HERNIA. L. F. Watson, M.D., F.I.C.S., 3rd edition. 732 pages. 323 illustrations. St. Louis: C. V. Mosby Co., 1948.

This edition of "Hernia" is a well-written, concise and profusely illustrated text on the subject of all types of hernias, as related to the abdominal portion of the body.

In the opening chapters the author discusses the general features of hernias occurring throughout the abdominal wall or in the abdominal cavity, and goes into considerable detail regarding anesthesia, surgical technique and the principles involved in treating complications.

Inguinal hernias are discussed completely throughout the text, and pathology and operative procedures are very well illustrated. All types of hernia repair in the inguinal region are considered and evaluated, with stress on the recurrence factors and the repair of the recurrent hernia. The various methods employed are thoroughly and concisely discussed, as well as the judgment involved in the choice of the type of repair to employ. The latter chapters of the book deal with the various types of hernias, such as ovarian, appendiceal, bladder and Meckel's diverticula hernias, as relating to the finding of these organs in the hernial sac. These are treated in detail, as they produce certain problems arising in the repair of the inguinal hernias.

The chapter on internal abdominal hernias is most interesting and complete. Each type is considered not only from the historical background, but as to definite operative procedures, the principles involved in the repair of the hernia, and how to correct it.

There are also chapters on the rare, seldom seen type of hernias, such as the obturator, sacral, perineal and lumbar types, which are completely discussed and illustrated. A chapter dealing with the injection treatment of hernias is complete, with a thorough consideration of the subject, and would be of interest

to any one interested in this phase of hernia repair.

One is impressed by the completeness of the text in treating the general subject of herniations, as they occur in the abdominal region. The material is up to date, and at the conclusion of each chapter there is a very complete bibliography containing the more recent medical literature, relative to the subject.

Because of the completeness with which the subject of hernias is treated in this text, this volume should be in the library of anyone doing general surgery, not only for reference, but also for general reading on any particular type of hernias with which he might be confronted and called upon to treat. As a reference book, its value cannot be stressed too strongly, the illustrations give a thorough presentation of the operative technique, as well as the pitfalls and complications in the surgical treatment of hernias.

E. W. Minty, M.D.

REMINGTON'S PRACTICE OF PHARMACY. Ninth Edition. Edited by Prof. E. Fullerton Cook and Eric W. Martin, Philadelphia College of Pharmacy and Science. 1500 pages. Mack Publishing Company, 1948, Easton, Pennsylvania.

The Ninth Edition of Remington's Practice of Pharmacy, for more than sixty years the outstanding authority on the science and profession of pharmacy, will be available about June 1. This famous book has been completely rewritten from cover to cover by outstanding authorities in every phase of pharmaceutical practice, including hospital, manufacturing and retail pharmacy, as well as the allied sciences upon which the profession is built. The book consists of 1500 pages of the most modern scientific information available concerning pharmacy.

Since 1885, the "Remington" has been the most popular textbook on pharmacy. Leafing through the pages of the many editions reveals the story of the development of the two closely associated professions, pharmacy and medicine. As each new revision appeared, the latest developments in these two sciences and related fields were presented in a concise manner. The growth of the book has been phenomenal, and the new revision had a particularly auspicious beginning when the heirs of Professor Joseph P. Remington, original author of the book, turned the copyright of the book over to his alma mater, the Philadelphia College of Pharmacy and Science, so

that the proceeds from its sales would be used for pharmaceutical education. The new edition is being translated into Spanish for distribution throughout South America, and will undoubtedly become the recognized authority on pharmaceutical practice in the entire Western Hemisphere.

The editor-in-chief of the ninth edition, Professor E. Fullerton Cook, internationally known as a teacher, editor and pharmacopœial authority, and the co-editor, Eric W. Martin, pharmaceutical and chemical consultant, have assembled an editorial staff of more than forty specialists, including experts in pharmacy, chemistry, the biological sciences, research, therapeutics, pharmacology, and practical pharmacy.

Never has a more comprehensive accumulation of up-to-the-minute information been blended by editors into such a logical presentation for educators, students, pharmacists, physicians, and agencies advertising pharmaceutical products.

In the ninth edition of the "Remington" will be found many newly developing phases of the biological, physical and chemical sciences. All the latest organic medicinals are extensively treated both from the chemical and therapeutic standpoint. The antibiotics (penicillin, streptomycin, et cetera), hormones, vitamins, surface active agents, quaternary ammonium bactericides, analgesics, anesthetics, sulfonamides, antihistaminic agents, amino acids, enzymes, steroids, and countless other subjects have all been treated comprehensively by a nationally known authority in each field.

The book is an unexcelled manual for teachers, a refresher course for the practicing pharmacist, a guide to modern therapeutics for the intern and physician, and a valued reference for pharmaceutical detail men, chemical firms, librarians and research workers.

PATHOLOGY OF TUMOURS. R. A. Willis, D.Sc., M.D., F.R.C.P. Sir William H. Collins Professor of Human and Comparative Pathology, Royal College of Surgeons, London; formerly Pathologist to the Alfred Hospital, Consultant Pathologist to the Austin Hospital for Chronic Diseases and Lecturer on the Pathology of Tumours in the University of Melbourne, Australia. 992 pages. Illus. London, England, Butterworth & Co. (Publishers), Ltd.; St. Louis, C. V. Mosby Company, 1948. Price $20.00.

As the author states, this book is the outcome of his special interest in tumors during twenty years as a hospital pathologist. Rather than give the usual didactic presentation of the subject, the author has given his own experience and even in controversial matters has plainly stated his own opinions. Of special interest are the chapters on the comparative pathology of tumors and experimental production of tumors.

Because of its general excellence, it is hard to select one chapter that is superior to another. The illustrations are exceptionally lucid; a workable index is listed. This book is highly recommended for the pathologist, the clinician and the student.

MODERN NURSING

SCHOOL OF PSYCHIATRIC NURSING

★

A one-year course is offered to girls over 17 years of age.

★

Small charge for matriculation, such as nurses uniforms, cape and other necessary incidentals.

★

June class now being formed

GLENWOOD HILLS HOSPITALS is currently offering to qualified applicants a one year course in psychiatric nursing. The course was originally laid out by a group of University of Minnesota professors and hospital staff members, and is the product of careful thought on their part. The curriculum has been streamlined to fit the modern needs of the modern methods of patient treatment. The subject matter has been consolidated and reduced to factual information directly applicable to the nurses work. The time necessary for completion was a foremost consideration. Only through an intensified course of this type can the training be accomplished in a short time and the student quickly released to a position of productivity within the profession.

The increased demand for nurses due to expanding hospitalization plans and the steady loss of trained nurses to marriage has resulted in an endangering shortage. This situation can only be rectified through your help and an accelerated program of training.

FREE ILLUSTRATED BOOKLET

AS A DOCTOR, you can materially assist in overcoming this shortage by enumerating the advantages of a nursing career to young ladies in your community. Glenwood Hills Nursing School has prepared an illustrated booklet describing in word and pictures the facilities available to the student nurse.

May we suggest that you fill in the card below with the name of a girl in your community who would be a potential candidate for the June class. Do this as your contribution in aiding the national drive to recruit more nurses.

GLENWOOD HILLS HOSPITALS

This baby's mother learned about Mead's Oleum Percomorphum from her physician, not from public advertising or displays.
"Servamus Fidem"
HOW much sun does the infant really get?
Not very much: (1) When the baby is bundled to protect against weather or (2) when shaded to protect against glare or (3) when the sun does not shine for days at a time. Mead's Oleum Percomorphum is a prophylactic against rickets available 365¼ days in the year, in measurable potency and in controllable dosage. Use the sun, too.
Mead Johnson & Co., Evansville, Ind., U.S.A.

BENADRYL

Therapeutic results reflect its abundantly documented background of basic research and clinical investigation. The great volume of reports on hand and ever increasing affords an imposing array of clinical data on BENADRYL.

The antihistaminic action of BENADRYL may be utilized in relieving the symptoms of hay fever, pollen asthma, acute and chronic urticaria, angioneurotic edema, erythema multiforme, contact dermatitis, pruritic dermatoses, dermographism, drug sensitization, serum sickness, physical allergy and vasomotor rhinitis.

BENADRYL HYDROCHLORIDE (diphenhydramine hydrochloride P. D. & Co.) in doses of 25 to 50 mg., repeated as indicated, is usually sufficient to bring relief. Available in a variety of forms to facilitate individualized dosage and flexibility of administration including Kapseals® of 50 mg. each, capsules of 25 mg. each, and a palatable elixir containing 10 mg. per teaspoonful.

Financial worry

We hope that you will never have to use what we have to offer for sale. Strange, isn't it? But to view it from a different angle we certainly have no desire to see you have a misfortune such as a fire—a robbery—an accident or some sickness. Yet the law of average is moving your way. The really strange thing is that few people do what they should to eliminate worries over financial loss. Just check yourself.

This misfortune might never happen to you. But isn't it wise to put away a little money each year into a plan of Accident and Health Insurance that is available to you through your Association so that you won't have to worry about financial loss?

Experience is the Best Teacher

Paul Ehrlich
(1854-1915)
proved it in chemotherapy

Paul Ehrlich, expanding on his knowledge gained as a pupil of Koch, concluded from his experiences in the staining of bacteria that there was a close chemical affinity between the cellular body and the stain. This idea led him to believe that specific drugs could be found which would kill invading pathologic organisms, without damage to the host. His conclusions helped create the science of chemotherapy, which is increasingly important today.

Experience is the best teacher in cigarettes too!

Yes! Experience counts—today as always. And with the thousands and thousands of smokers who have tried and compared many different brands of cigarettes, Camels are the "choice of experience."

Try Camels yourself! See how your taste welcomes the rich, full flavor of Camel's choice, properly aged, expertly blended tobaccos. And see how your throat appreciates Camel's cool, cool mildness.

Let your own experience tell you why *more people are smoking Camels than ever before.*

R. J. Reynolds Tob. Co., Winston-Salem, N. C.

According to a Nationwide survey:

More Doctors Smoke CAMELS
than any other cigarette

Three independent research organizations in a nationwide survey asked 113,597 doctors to name the cigarette they smoked. More doctors named Camel than any other brand.

MUTUAL BENEFIT HEALTH AND ACCIDENT ASSOCIATION OMAHA

Lifetime Benefits

Non-Cancellable and Guaranteed Renewable Features

- Pays benefits for both sickness and accidents.
- Carries full waiver of premium for total permanent disability.
- Policy pays disability benefits regardless of whether disability is immediate.
- Policy does not automatically terminate at any age.
- Monthly benefits, $400.00; double indemnity, $800.00.
- Additional benefits, $200.00 per month while in hospital.
- Additional benefits, $200.00 per month for nurses care at home.
- Accident death benefits, $10,000.00; double indemnity, $20,000.00.
- Mutual Benefit and United Benefit licensed in every state in the U.S.A.

A Special Disability Program for Your Professional Group

UNITED BENEFIT LIFE INSURANCE COMPANY

Address: Professional Group Dept.; 420 Plymouth Bldg. Minneapolis Minn.

Notice: This Special Policy available only through Professional Group Department Representatives. Authorized registrars will carry a letter of identification signed by State Manager, Professional Group Dept.

Special Notice to Members

This Disability UPG20 Program shown on the opposite page, extended to the Minnesota State Professional Groups is a program that provides protection which gives Lifetime Benefits and is not subject to cancellation on account of age leaving you without protection when your loss of time is most valuable. It pays benefits for one day or more and covers permanent total disability. This UPG20 Program pays for every injury or accident, even Commercial Air Line travel is fully covered. It covers all sickness and every disease except insanity and venereal diseases. The maximum benefits are $600.00 monthly and its minimum benefits are $200.00 monthly for any illness. Accident benefits pay double indemnity for travel accidents on a common carrier, excepting air travel, which pays only the regular indemnity benefits.

To broaden the benefits while this UPG20 Program is in operation, the following limitations, common to most policies, have been omitted and are not a part of these policies.

(1) The Company's right to cancel the policy at any time — (Standard Provision No. 16).

(2) The Company's right to terminate the policy at a certain age — (Standard Provision No. 20).

(3) The Company's right to refuse renewal of policy to any individual practicing member of your group is forfeited except for non-payment of premium on or before due date.

(4) The Company's power to impose a Rider, eliminating the benefit for something that may happen or develop to render you an undesirable, or un-insurable risk, is canceled thru the elimination of each of the above.

The Minnesota enrollment is proceeding most satisfactorily, but it is the desire of the Companies, not only to conduct the enrollment in the manner found to be most successful for completing the group, but with full consideration for the policy and practice of the Minnesota Professional Associations mentioned.

Most Professional Groups, Associations, or Societies find it inexpedient to make specific endorsement of any company or plan to its members. It is the practice of the Mutual Benefit Health and Accident Association and the United Benefit Life Insurance Company both of Omaha, to submit their Disability Plan to the individual members of the group for their personal consideration. This has proven to be the most successful way to complete the enrollment of members of these groups since it brings about a decidedly better understanding of the plan to the members and, thereby, increases the ultimate total enrollment.

Therefore, should any Authorized Registrar, or Mutual Benefit Salesman represent that he is from either of the designated Associations, or that this plan has been endorsed by either Association, will you kindly report same together with the name of the representative to State Manager, Professional Group Department, 420 Plymouth Bldg., Minneapolis, Minn. —Phone AT. 2579.

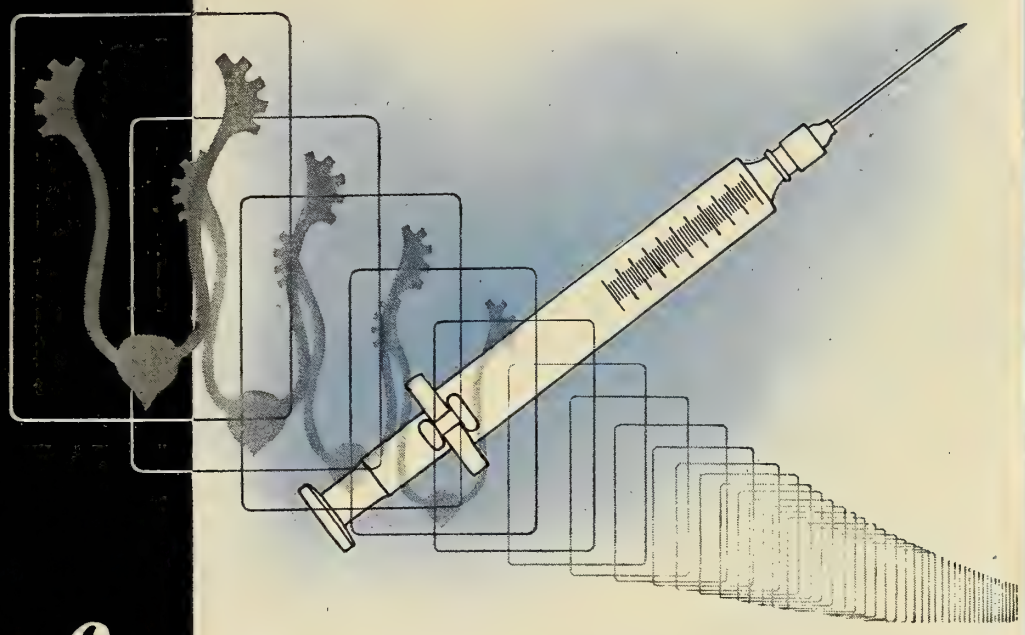
ESPECIALLY DURING

Post-Infectious Recovery

Following recovery from severe infectious disease, acute nutritional deficiencies must be corrected promptly if maximum speed of recovery is to be attained. The nutrient imbalance which exists during this period usually involves not only members of the vitamin B complex, but also proteins as well.

The delicious food drink made by mixing Ovaltine with milk is a pleasant and effective means of increasing the intake of virtually all essential nutrients. Easily digested and of low curd tension, it does not impose an undue digestive burden, and is frequently acceptable when other foods are refused. Three glassfuls daily supply significant amounts of B complex and other vitamins including ascorbic acid, biologically adequate protein, readily digested fat and carbohydrate, and the important minerals copper, iron, and calcium. This dietary supplement is enjoyed by all patients, young and old, and is taken without difficulty in recommended amounts. Hence it might well be included routinely in the dietary of convalescence.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.



Ovaltine

Three servings daily of Ovaltine, each made of ½ oz. of Ovaltine and 8 oz. of whole milk,* provide:

CALORIES	669	VITAMIN A	3000 I.U.
PROTEIN	32.1 Gm.	VITAMIN B_1	1.16 mg.
FAT	31.5 Gm.	RIBOFLAVIN	2.00 mg.
CARBOHYDRATE	64.8 Gm.	NIACIN	6.8 mg.
CALCIUM	1.12 Gm.	VITAMIN C	30.0 mg.
PHOSPHORUS	0.94 Gm.	VITAMIN D	417 I.U.
IRON	12.0 mg.	COPPER	0.50 mg.

*Based on average reported values for milk.

Safe for injection

The safety record of NEO-IOPAX* — Schering's brand of sodium iodomethamate for intravenous urography — is noteworthy: more than fifteen years of effective urinary tract visualization *without a single fatality* reported in the literature. The relative safety of

NEO-IOPAX®

(*disodium N-methyl-3,5-diiodo-chelidamate*)

is due to its unique composition and stability, the meticulous care exercised in its preparation, the careful control of all manufacturing stages, and the rigorous inspection of the finished product. Each ampul of NEO-IOPAX is sterile and free from foreign particles.

NEO-IOPAX is available in 10, 20 and 30 cc. ampuls of 50% concentration and 10 and 20 cc. ampuls of 75% concentration. Packaged in boxes of 1, 5 and 20 ampuls.

From the day that powerful, short-acting Pentothal Sodium was first introduced by Abbott in 1934, the index of reports on its use for intravenous anesthesia has grown rapidly. Coming from every corner of the globe, from every land in which modern surgery is practiced, the file of literature on Pentothal Sodium now lists more than 1070 reports, 90 of which were published last year. This worldwide record—impressive tribute to an anesthetic developed by a single commercial laboratory—covers every phase of the use of Pentothal Sodium: indications and contraindications, advantages and disadvantages, techniques of administration and precautions to be observed. With such a guide, Pentothal Sodium can be employed for intravenous anesthesia safely, effectively and conveniently. Interested in more information about this product? Just drop a line to Abbott Laboratories, North Chicago, Illinois.

FOR INTRAVENOUS ANESTHESIA

Pentothal® Sodium

(STERILE THIOPENTAL SODIUM, ABBOTT)

A NEW MOTION PICTURE FILM on the uses and limitations of Pentothal Sodium anesthesia in obstetrical procedures is available to medical groups. Write to Abbott Laboratories, North Chicago, Ill.

PROTEINS...

Pre- and Post-operative

"Surgical patients in many instances tend to come to operations in a depleted state. There are many reasons for this: chronic gastro-intestinal disease . . . long-standing infectious processes . . . or loss of blood. The preparation of the patient for surgery includes nutritional preparedness. In the first instance, this means a good supply of *proteins* and carbohydrates.

"The operation itself and the reaction of the body to it in the immediate convalescent period are likely to increase breakdown of body protein. There seems little doubt that the recent stress upon maintenance and supplementation of dietary protein has had a beneficial effect upon the period of convalescence and the incidence of complications."*

SWIFT'S STRAINED MEATS

Palatable protein supplementation for patients on soft, smooth diets

When surgery or disease creates a problem in protein supplementation, many physicians now use Swift's Strained Meats. These all-meat products provide an abundant and palatable source of complete, high-quality proteins, B vitamins and minerals. Originally developed for infant feeding, the meats are strained fine—may easily be used in tube-feeding or for oral feeding in soft diets. Swift's Strained Meats are convenient to use—ready to heat and serve. Six kinds provide variety and tempting flavors that help combat anorexia: beef, lamb, pork, veal, liver and heart. 3½ ounces per tin.

*"*The Importance of Protein Foods in Health and Disease*"—new, physicians' handbook on protein-feeding. Prepared by a physician, in conjunction with the Nutrition Division of Swift & Company, this booklet will be sent you free on request. Simply fill out the coupon.*

Also Swift's Diced Meats—for high-protein diets requiring foods in a form less fine than strained, these tender, juicy pieces of meat are highly desirable.

Picture this on your office wall!

Here is a message every patient should see. It appears in full color in LIFE and other national magazines—reaching more than 23 million people.

Would you like a copy for your reception room? Write to Parke, Davis & Company, Detroit 32, Michigan.

Some things you should know about being a good patient

No. 212 in a series of messages from Parke, Davis & Co. on the importance of prompt and proper medical care.

FOR your own sake, as well as your doctor's it is vitally important to be a "good patient."

Often it is your co-operation with your doctor that makes the difference between an early recovery and a late one, between a minor illness and a serious one.

Here are some of the ways you can help your doctor, and yourself

1. If you feel sick, call your doctor at once. Don't wait for a serious illness to develop before you ask his help. The sooner he sees you, the more he can do to help you avoid a major illness.

2. Before you telephone your doctor, make a list of the questions you want to ask him. Have a paper and a pencil handy when you call, so that you may take down his instructions. This way you will save your doctor's time, and remember *accurately* what he tells you.

3. Answer your doctor's questions *fully*. A previous illness may not seem to you to have any bearing on your present condition. But to your doctor it might furnish a valuable clue. Tell him complete facts. Let *him* decide what is important.

4. Follow your doctor's instructions *exactly*. If he prescribes medicine, take it *according to directions*. Remember, a larger dose than that prescribed won't cure you faster. And it might be harmful.

5. Never use medicine prescribed for somebody else, or for a previous illness of your own. However similar your symptoms may appear to you, the nature of your illness may be quite different. Only your doctor can accurately diagnose your trouble and prescribe proper treatment.

6. If your doctor advises an operation, don't put it off. With modern surgery, modern hospital care, you seldom have reason to fear an operation.

7. The new medical treatments you read about in the popular press aren't likely to be news to your doctor. If your doctor has not recommended a new treatment to you, it is probably because there are still some questions about its value, some limitations not stressed in popular reports, or some factors in your case which would make the treatment undesirable or ineffective for *you*.

8. Don't ask your doctor to advise you about members of your family whom he himself has not seen. He cannot risk giving an opinion about a patient of whose condition he has no firsthand knowledge.

PRENATAL SUPPORTS

CAMP

Of the so-called minor complaints of pregnancy, a contributor to the medical literature* makes the following statement concerning backache—

"Backache seemed to be due to several causes. Strain of the lumbar muscles and the vertebral ligaments, due to a change in the center of gravity was often responsible; fallen arches aggravated the complaint. It was relieved by rest in bed. A maternity corset with moderately rigid stays in the back was of benefit . . . Sacro-iliac relaxation as evidenced by pain over the joint was usually unilateral and was referred along the sciatic nerve. Usually a maternity corset would relieve it. This corset should have a strap or other device that will pull it snug over the sacro-iliac region."

Charles J. Marshall New York Journal of Medicine, Vol. 34, Aug. 15, 1934

Camp prenatal supports are unique in that the overstrap with its buckle (through which the lacings ply) allows the support to be drawn evenly and firmly about the pelvis; thus the pelvic joints are protected and steadied.

From such a foundation, the back of the patient is well supported and the abdominal muscles are aided in holding the increasing load in position.

But... WET DUST CANNOT FLY!

Did you ever notice the fine layer of dust that settles on tables, chairs, and other polished furniture after you finish vacuuming? That is because dust has been taken out of the carpets and upholstered furniture and blown into the air through a porous bag.

Rexair uses an entirely new principle of cleaning. This principle is based upon the fact that *wet dust cannot fly.*

When Rexair takes dust from the carpets, from floors, from upholstered furniture, it immediately drowns that dust in water. Clean, "washed" air is then returned to the room.

The longer the Rexair runs, the cleaner and fresher the air becomes, because Rexair actually removes dust from the air you breathe. Rexair has no dirty bag to empty. You pour the water down the drain, and pour the dirt away with it.

Rexair

LILLY *Biological Refrigerator*

38° Fahrenheit for storage of biologicals—with heavy lock for security.

The professional office size refrigerator for storage of biological drugs and serums

- White enameled cabinet made of heavy gauge aluminum.
- Convenient, compact size matches other furniture.
- Maintains 38° F. temperature. Automatic thermostatic control.
- Freezing section with ice tray. Chrome-plated basket drawers.
- Large storage space for bottles or packages.
- Sealed, standard cold unit requires no lubrication or service.
- Guaranteed for one year.

Designed and Built for the Modern Physician's Office

The Lilly Biological Refrigerator is a fine piece of professional furniture — an asset to any modern physician's office. **Price $150.00**

The First Vaccination....

Both Medicine and Dentistry must thank Edward Jenner (1749-1823) for direct and indirect contributions to the professions' progress in the *prevention* of disease.

Smallpox was deadly; but so was its "prevention" by inoculation, brought from Turkey to England in 1718. Then rumors spread through the Gloucestershire countryside that milkmaids who had suffered *cow*pox were immune to *small*pox. With his successful vaccination of little Jimmy Phipps, using matter from the infected hand of Dairymaid Sarah Nelmes in 1796, Jenner had the *proof.*

Disease could be prevented! Not only smallpox, diphtheria, scarlet fever and typhoid, but diseases of the mouth as well—thanks to Jenner's contemporary, the French dentist, Jean-Baptiste Gariot.

Prevention Today, for most physicians and dentists, includes more than prevention of disease. It includes prevention of the helplessness and injustice which the doctor knows would attend most malpractice claims or suits—if it were not for the *preventive* counsel, *confidential* service and *complete* protection assured by the Medical Protective policy, developed through nearly 50 years' experience.

MANAGEMENT OF RHEUMATIC FEVER AND RHEUMATIC HEART DISEASE

BENEDICT F. MASSELL, M.D.
Associate Research Director, House of the Good Samaritan
Boston, Massachusetts

THE phase of the rheumatic fever problem which will be discussed in this paper is a broad one. "Management of rheumatic fever and rheumatic heart disease" involves a consideration not only of the treatment of acute or active rheumatic fever but also the treatment of congestive heart failure associated with active rheumatic fever. Furthermore, because of the repetitive nature of rheumatic fever, any intelligent discussion of management should include a consideration of possible methods for the prevention of rheumatic fever recurrences.

Treatment of Rheumatic Fever

At the outset, it must be stated that unfortunately there is no specific treatment for rheumatic fever. Most of the therapeutic measures therefore aim at (1) building up body resistance and protecting the heart as much as possible from undue strain until the rheumatic process is overcome by natural mechanisms or subsides of its own accord, (2) keeping the patient comfortable and happy, and (3) protecting the patient against episodes which can cause an increase in the activity of the rheumatic process. In this discussion, consideration will be given not only to such procedures as may bring about improvement but also to those which are of no value or which may even cause untoward reactions; for in the treatment of rheumatic fever it is just as important to be cognizant of what may be harmful as it is to know what may be beneficial for the patient.

From the House of the Good Samaritan, Boston, Massachusetts. Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1947.

Bed Rest

Bed rest is probably one of the most important of all therapeutic measures for rheumatic fever. Although available statistics comparing the results of treatment by long bed rest with the results of those in which there was no bed rest are scanty, clinical experience strongly suggests that patients do better with rest. It would appear that rest encourages the building up of body resistance in rheumatic fever patients just as it does in patients with other diseases. Furthermore, when the body is at rest, the heart does not beat as rapidly as it does at other times, and the mechanical strain on the heart is reduced to a minimum. Generally it is advisable to continue bed care until all evidence of active rheumatic fever has disappeared. This means waiting not only until joint pains, fever, nodules, and other clinical signs of the disease have subsided, but also until any abnormality of conduction time in the electrocardiogram has disappeared and until the sedimentation rate has fallen to within normal limits. Because of the frequently cyclic nature of rheumatic fever, it is advisable to have a normal temperature chart and three or four normal sedimentation rate determinations over a period of one to two months before accepting these findings as evidence that the rheumatic process has disappeared.

The total duration of this rest regimen should depend on the duration of active rheumatic fever. Because of the chronicity of the disease and because of the frequency of cardiac involvement in children, it probably is wise to advise a minimum of three months of bed rest for every child

with an established diagnosis of rheumatic fever. In many individuals the rheumatic process continues for as long as six months to a year and in rare cases for several years or longer. In such instances, rest should be maintained for a corresponding length of time.

Two exceptions to these recommendations are occasionally indicated.

1. Adults who develop rheumatic fever for the first time and who show no evidence of heart involvement are not likely to develop heart damage at a later date. With such individuals, therefore, it is safe to be more lenient and allow gradually increasing physical activity when the clinical signs of disease have subsided even though abnormal laboratory findings may still be present.

2. In some children and young adults the sedimentation rate gradually falls in conjunction with clinical improvement but levels off above the accepted upper limit of normal and continues at this abnormal level month after month even though the patient is otherwise entirely well. In some instances these apparently abnormal sedimentation rates eventually come down to within normal limits. In other instances they may continue for as long as three or four years or even longer. Although such persistently elevated sedimentation rates, even in the absence of other evidence of active rheumatic fever, may indicate a low-grade rheumatic process, nevertheless it usually is not practical to continue the bed rest regimen for a correspondingly long period. Therefore, when the sedimentation rate persists at an abnormal level and shows no further trend in a downward direction, it is reasonably safe to allow gradually increasing physical activity, provided that there has been a total of at least six months in bed and at least three or four months of freedom from clinical signs of active rheumatic fever, and provided that there has been no progression of the cardiac damage during this period.

When the time has arrived to allow the patient out of bed, it is wise to make the transition from bed rest to physical activity a gradual one. This gradual method of increasing time up allows the patient to adjust himself better to physical activity and allows for the detection of any untoward reactions to physical activity before harmful effects can be incurred.

Diet, Vitamins, and Iron

Although no definite relationship has been established between diet and the onset of rheumatic fever, proper diet does appear to contribute towards improvement in some patients. Additional vitamins and iron or iron-and-liver preparations are of questionable value but can do no harm. Usually the anemia which is often associated with rheumatic fever will not improve until the active rheumatic process subsides.

Salicylates

Although salicylates have been used for many years as a remedy for rheumatic fever, there is still disagreement among physicians as to their exact virtues. All agree that salicylates are of great value for symptomatic relief. The drug reduces fever promptly, so that within a few days of starting therapy the temperature can be brought down and maintained within normal limits. In addition to this antipyretic effect, salicylates have a striking effect on the joint manifestations. As a rule, pain and tenderness quickly disappear, and even joint swelling subsides relatively soon.* Salicylates may also relieve other pains, such as those in the precordium, chest, back, and abdomen. Finally, there is suggestive evidence that the drug may occasionally reduce the amount of effusion associated with pericarditis. Salicylates in small or moderate dosage, sufficient to reduce fever and relieve pain, may also reduce an elevated leukocyte count but do not appreciably lower the erythrocyte sedimentation rate.

Over a period of years, physicians had come to believe that, although salicylates by these effects could make rheumatic fever patients feel much more comfortable, their use did not actually shorten the course of the disease nor reduce or prevent heart damage. However, in 1943, Dr. Alvin Coburn suggested that the customary doses of salicylates, although productive of symptomatic relief, were too small. He observed that, where the drug was given in massive doses and where therapy was started soon after the onset of the disease, the duration of the rheumatic process could be shortened considerably and heart damage could be prevented. When given in this way, the drug was found to reduce the erythrocyte sedimentation rate as well as the temperature to within normal limits.

*Murphy would probably disagree with this statement. He failed to observe any appreciable effect of salicylates on joint swelling.

To obtain this remarkable effect, Dr. Coburn considered it necessary to give sufficient salicylate to produce a blood concentration above 35 mg. per 100 c.c. He also advised that the drug be administered intravenously during the first few days of therapy in order that the high salicylate blood level be obtained promptly. Others likewise reported favorable results with massive oral salicylate therapy, but unfortunately most investigators have not been able to equal Dr. Coburn's good results. They have not found very large doses more beneficial than the dosage necessary for symptomatic relief. Even with blood levels above 35 mg. per 100 c.c., the duration of the rheumatic process has not been observed to be shortened, nor has the incidence or degree of heart damage been reduced. Although in some instances the sedimentation rate has been brought to within normal limits by high blood concentrations of salicylate, when the drug therapy was discontinued the rate soon returned to the same level that it would have been had salicylates not been given. Furthermore, it now appears that the effect of salicylates on the sedimentation rate is nonspecific and that it may be the result of a toxic action on the liver. Some investigators have occasionally observed such severe toxic reactions from massive therapy that they feel the procedure is a dangerous one.

It appears, therefore, that the virtues of salicylate therapy are still not clearly defined. The drug in moderate doses is certainly of value for symptomatic relief. The answer to the question of whether very large doses given early in the course of the disease will or will not actually produce permanent beneficial results must await further investigation. Therefore, until the question is definitely answered, it would seem advisable to give salicylates in sufficient dosage only to produce relief of pain and to reduce high fever. The drug, in moderate doses, probably should also be given to rheumatic fever patients with pericarditis.

It is important to point out that salicylates, by relieving joint pains and abolishing fever, may mask two very important manifestations of rheumatic fever and thus may produce a false sense of security both for the patient and for the physician. Because of this camouflaging effect, salicylates should not be given to patients who do not require symptomatic relief or who do not have pericarditis. Furthermore, even when use of the drug is indicated, the therapy should not be continued month after month without occasionally discontinuing the treatment so that the presence or absence of pain and fever may be determined.

Finally, it is evident that as long as the patient is receiving salicylates, the absence of pain and fever is not necessarily an indication of the subsidence of the rheumatic process. In fact, because of the possible cyclic course of rheumatic fever, at least three or four weeks of freedom from pain and fever should elapse after the omission of salicylates before accepting the fact that these manifestations have completely disappeared.

In connection with the omission of salicylate therapy it is well to call attention to an occasionally observed phenomenon which may be described as a withdrawal effect. The abrupt discontinuance of the drug after a period of several weeks or more of treatment may be followed by the appearance of fever which subsides again spontaneously within three or four days and does not recur. This transient fever may be very difficult to interpret. It usually can be avoided by reducing the dose of salicylates gradually over a period of one or two weeks before finally omitting it altogether.

Methods of Administration.—Salicylates may be given by mouth, by rectum, or by the parenteral route. The intravenous injection of sodium salicylate is usually unnecessary, for even the high blood levels advocated by Dr. Coburn can be readily and quickly obtained when the drug is given by mouth. Although absorption of salicylates from the rectum is said to be poor, clinical experience suggests that it is sufficiently good to produce relief of pain in many instances, and hence this route may be utilized in patients who are vomiting. When sodium salicylate is given in this way, rectal irritation can be prevented to some extent by dissolving the drug in cornstarch solution.

For administration by mouth, a route suitable for most patients, either sodium salicylate or aspirin may be used. In my experience the latter is less likely to cause gastric irritations and, therefore, is the preparation of choice. Any salicylate preparation when given in large doses may produce vomiting by a central action, irrespective of the route of administration.

Dosage.—Whether salicylates are given as sodium salicylate or as aspirin, the dosage is approxi-

mately the same. For the relief of symptoms it usually is necessary to give between 0.030 and 0.045 gram (½ and ¾ grain) per pound of body weight every twenty-four hours. Thus a 50-pound child might require between 1.5 and 2.5 grams (25 and 40 grains) per day, and a 150-pound adult might require between 4.5 and 7.0 grams (75 and 110 grains). Some individuals may actually require less than this dose; whereas others, especially adults with severely swollen and tender joints, may require a somewhat larger dose for relief. In general, it is better to start with the average requirement and then, if necessary, increase or decrease the dose according to the clinical response of the patient. For the relief of symptoms it usually is not necessary to administer salicylates during the night. A simple routine is to divide the total daily amount into four to six doses and to give one dose every three or four hours while the patient is awake.

Toxic Effects of Salicylates

Allergic Reactions.—There are occasional individuals who are hypersensitive to aspirin. Apparently idiosyncrasy to this derivative is more common than to other salicylate compounds. Even small doses of the drug may be followed by allergic-like reactions, such as swelling of the nasal mucosa, puffiness of the eyes, and even asthma. Deaths after the ingestion of small quantities of acetylsalicylic acid, though fortunately rare, have been reported. These hypersensitivity reactions can usually be avoided by taking an adequate history and by not giving the drug to persons who report previous reactions. In rare instances when a patient has never previously taken aspirin or other salicylate preparations, and in those instances when a suspicious but inconclusive history of aspirin idiosyncracy has been elicited it is safe to administer a test dose of 0.3 grams (5 grains), and if there is no untoward reaction after several hours, the amount may be gradually increased to that which is desired.

Epigastric Distress, Nausea, and Vomiting.—Clinical experience suggests that these symptoms are usually due to direct gastric irritation, though a recent study would seem to indicate that the action may be entirely central. Although large amounts of salicylate are usually required to produce vomiting, occasional individuals are susceptible even to small doses. As a rule, aspirin is better tolerated by the stomach than sodium salicylate. To prevent gastric symptoms it is customary to give sodium bicarbonate in equal dosage, but in patients with severe heart damage it is better to avoid the administration of sodium because of the danger of causing fluid retention. Therefore, under the latter circumstances, the use of enteric-coated preparations is preferable when gastric irritation is a problem.

Tinnitus.—Even when salicylates are being given in only moderate dosage for the relief of symptoms, some patients will complain of ringing in the ears. This annoying reaction will often decrease and sometimes disappear after several days even though the medication is continued. If, however, the ear symptoms continue, and if they are very bothersome to the patient, it may be necessary to omit the drug entirely for twenty-four hours and then resume it in smaller amounts. Often a reduced dosage can be found which will not produce tinnitus and at the same time will be sufficient to control pain and fever.

When large doses of salicylates are given, tinnitus occurs more frequently and in a more severe degree. In addition to ringing in the ears, actual deafness may be produced. When this happens, it is well to omit therapy entirely for one or two days and then resume it with smaller doses. However, if large amounts of salicylate are necessary for the control of severe symptoms, it is comforting to know that permanent salicylate deafness has not been reported.

Hypoprothrombinemia.—Salicylates have been shown to cause a reduction of plasma prothrombin. Furthermore, post-mortem examinations of persons dying of salicylate intoxication have occasionally revealed the presence of capillary hemorrhages in the brain and in other organs. In spite of these observations there is generally no need for concern when salicylates are administered in small or moderate doses, for actual bleeding as the result of therapy is rarely, if ever, encountered, the prothrombin-depressing effect is sometimes only temporary even though treatment is continued, the lowering of prothrombin does not occur in all patients receiving the drug, and reduction of prothrombin to a critical level has not been observed except in association with extremely high plasma salicylate concentrations.

Rheumatic fever patients who happen to be receiving salicylates occasionally may also be sub-

ject to nose bleeds and rarely may have petechial skin hemorrhages or other signs of bleeding. Under these circumstances, even though there may be no actual proof of a causal relationship between the bleeding and the therapy, it probably is advisable as a precautionary measure to administer vitamin K. In spite of one opinion to the contrary, most reports suggest that the prothrombin-depressing effect of salicylate can be corrected and prevented by this vitamin. About 1 milligram of synthetic vitamin K is said to be needed for each gram (15 grains) of salicylate. Commercial preparations of aspirin which have vitamin K incorporated in the tablet are available.

Hyperpnea and Alkali Reserve Depletion—Hyperventilation is an important sign of serious salicylate intoxication and is an indication for the immediate omission of therapy. It must be distinguished from cardiac dyspnea. In hyperpnea the patient takes deep and rapid breaths and yet does not have any subjective symptoms of air hunger. Usually the patient can lie flat, and cyanosis is absent. The urine may or may not contain acetone.

Although the mechanism of salicylate hyperpnea is not entirely understood, it appears to involve a direct or reflex stimulating effect of the salicylate molecule on the respiratory center. With overventilation, carbon dioxide is blown off, and there is a compensatory excretion of alkaline urine. The net result is a reduction of the blood bicarbonate and often a rise in the pH. Apparently in occasional cases ketosis develops secondarily (as evidenced by the presence of acetone in the urine), and this in turn produces further depletion of the alkali reserve.

Fortunately, hyperpnea and serious depletion of the alkali reserve is usually encountered only when very large doses of salicylate are being administered. However, it occasionally occurs when the drug is being given in only moderate amounts for the control of symptoms, so that one should always be alert to its possible development. Children seem to be somewhat more susceptible than adults to this untoward reaction.

Whenever hyperpnea occurs, salicylate therapy should be discontinued immediately and continuously until all signs of the reaction have disappeared. Then, if salicylates are still necessary, they should be resumed in smaller dosage. Although the administration of sodium bicarbonate will increase the blood bicarbonate concentration, it may also raise an already elevated pH to a dangerous level. Furthermore, the administration of sodium to patients who have severe heart damage may precipitate congestive failure by increasing the retention of fluids. For these reasons it probably is safer not to treat salicylate hyperpnea with sodium bicarbonate or other alkalis. The simple administration of sweet drinks by mouth, in addition to the omission of salicylates, is sufficient therapy in most instances.

Sulfonamides and Penicillin

Sulfonamides do not favorably affect the course of established active rheumatic fever; on the contrary, these drugs often seem to increase the activity of the rheumatic process or cause toxic reactions. Hence, the administration of sulfonamides is contraindicated in the presence of active rheumatic fever.

Penicillin likewise has no beneficial effect upon the course of rheumatic fever, and, therefore, it also is of no value as a therapeutic agent. Although some investigators believe that penicillin may aggravate active rheumatic fever, it has been my experience that most patients can tolerate the antibiotic, especially if it is given for periods of only a week to ten days. Because of its apparent harmlessness, penicillin, in contrast to sulfonamides, can be given to patients who have active rheumatic fever and who also have or are suspected of having some other condition for which the antibiotic is known to be therapeutically effective.

The ineffectiveness of sulfonamides and penicillin for the treatment of active rheumatic fever should not be confused with the possible virtues which these drugs may have for the prevention of rheumatic fever recurrences. Furthermore, there is suggestive evidence that, in patients with active rheumatic fever, flare-ups of the disease may be prevented, and the course of the illness may be favorably influenced by the early use of penicillin therapy for all intercurrent hemolytic streptococcal respiratory infections. This aspect of the problem will be discussed more fully when possible methods for the prevention of rheumatic fever are described.

Home School and Occupational Therapy

Rheumatic fever is a subacute or chronic disease. Recovery from the acute attack and con-

valescence usually take many months, during which time the patient cannot of course attend school. Rheumatic fever is also a repetitive disease, and, hence, further loss of time from school is caused by recurrences. Because of these prolonged absences, the rheumatic child is sometimes obliged to repeat grades and to attend classes with children considerably younger than himself. A frequent result of this unfortunate situation is that the child loses interest in continuing his education and develops a feeling of inferiority.

A very important part of the treatment of rheumatic fever, therefore, is the provision for such home instruction as will keep the patient abreast of his school studies. In many cities the school system provides home teachers who will visit the child two or three times a week. Except during the more acute stages of the disease, most patients are not too ill to study in bed, and with adequate instruction many make such excellent progress that they are able after recovery to return to the grade of school to which they would normally have been promoted had their attendance not been interrupted by illness.

Patients who do not feel very ill find the long months of bed rest extremely monotonous. Although home schooling somewhat relieves the monotony, recreational activities contribute the most toward keeping the child happy. In this field the occupational therapist usually proves invaluable. However, many arts and crafts can be taught to a child by his parents if a professional instructor is not available.

Treatment of the Heart: Congestive Failure

Most patients with active rheumatic fever do not require treatment directed towards the heart itself. Although it is true that bed rest may benefit the heart by reducing the amount of its work and its speed, even rest is chiefly of value because it stimulates the body's natural resistance to the rheumatic process. The heart itself requires treatment only if there is congestive failure, pericardial effusion with tamponade, or disturbances of rhythm such as auricular fibrillation. Tamponade resulting from rheumatic pericarditis fortunately is rarely encountered, and the treatment of disturbances of rhythm is essentially the same as when these conditions occur in association with other kinds of heart disease. Hence the limited time which is available will be devoted to the problem of congestive failure associated with active rheumatic fever.

Bed Rest

Bed rest, an obvious part of the treatment of congestive heart failure, has already been discussed under the treatment of active rheumatic fever. In the presence of congestive failure, the rest regimen should be as strict as possible. The patient should be allowed to lie flat or to sit up against a back support, whichever gives more comfort.

Salt Restriction

In the presence of congestive failure, restriction of sodium tends to increase the urinary output, while the ingestion of sodium increases the retention of fluids. A maximum diuretic effect is obtained with a so-called "salt-free" diet in which the daily amount of ingested sodium chloride is restricted to 2 grams (30 grains). In order to obtain this minimum intake, it is not only necessary to refrain from the addition of salt at the table and in cooking but also to select foods which are very low in salt content.

Food which is so nearly salt free tastes extremely flat. Powdered ammonium chloride shaken on sparingly from a pepper shaker may contribute a slightly salty taste, but too much of this causes a bitter taste. Spices and salt-free condiments may also improve the taste of the food slightly. Even with the use of these salt substitutes, the diet will still not be very palatable, and many patients will not eat or will eat very poorly. Since an adequate food intake is an important part of the treatment of the active rheumatic process, a diet which is too restricted in salt may defeat its own purpose. Therefore, for patients who will not eat a "salt-free" diet, it is advisable to be more lenient and to prepare for these individuals a diet which is relatively low in salt content but which is still palatable.

Fluid Restriction

It is still customary with many physicians to restrict the fluid intake of cardiac patients who are in congestive failure. However, if the salt content of the diet is sufficiently low, fluid restriction is not necessary, since without sodium, excess amounts of fluid will not be readily retained in the body. Furthermore, patients who are suffering from an active inflammatory process such as rheumatic fever become dehydrated if their fluid intake is too strictly curtailed. It is, therefore, generally advisable to allow rheumatic fever patients to drink as much as they wish,

especially if their salt intake is low. Most patients who do not ingest much salt will not desire excess amounts of fluid.

Theobromine Diuretics

These substances, which belong to the xanthine group of drugs, provide us with one of our most effective weapons for combating congestive failure when it occurs in the course of active rheumatic fever. There are several different theobromine preparations which are available for oral use. Most of them are obtainable in 0.5 gram (7½ grain) tablets, and the daily dose varies from 1.5 grams (22½ grains) to 4 grams (60 grains), depending on the size of the patient and the diuretic response. The drug is most effective when given in three or four divided doses per day and when administered daily until the need for it is no longer present. Many patients have been given theobromine diuretics every day for three or four months or longer without any untoward reaction and without any loss of the drug's diuretic activity. The percentage of rheumatic fever patients whose congestive failure can be kept under control by this diuretic is extremely high, especially if the drug is used in conjunction with a salt-restricted diet.

Of the available theobromine diuretics which I have tried, theobromine calcium salicylate (Theocalcin) is the most satisfactory. It is essentially nontoxic, and it is extremely well tolerated by the gastrointestinal tract, practically never causing nausea or vomiting even when given in as large doses as 1 gram (15 grains) three times daily to small children. The disadvantage of Theocalcin is its relatively high cost. One should also keep in mind that this drug contains about 35 per cent salicylate, and that 1 gram (15 grains) is equivalent in salicylate effect to 0.5 gram (7½ grains) of aspirin.

Another well-tolerated preparation is theobromine sodium acetate, which is made up in a specially enteric-coated tablet and sold under the trade name of Theosodate. Like Theocalcin, it does not cause nausea or vomiting and often produces a good diuretic response. However, it has the disadvantage of containing sodium, which should be avoided for patients who already have a tendency toward fluid retention.

Plain theobromine is relatively cheap and is an effective diuretic, but it frequently causes gastric irritation with consequent nausea and vomiting.

Theobromine sodium salicylate (Diuretin) is another relatively cheap and often effective diuretic, but it also is poorly tolerated by the gastrointestinal tract and, in addition, has the disadvantage of containing sodium. Its chief value is in the treatment of patients for whom a theobromine diuretic is desired but who, because of vomiting, cannot be given medication by mouth. To these patients theobromine sodium salicylate, which is water soluble, can be given by rectum in small retention enemata.

Ammonium Chloride

Ammonium chloride by itself has a mild diuretic action, but its chief use is in conjunction with the administration of mercurial diuretics, the action of which it seems to enhance. To be effective it must produce an acid urine. Ammonium chloride is obtainable in enteric-coated tablets of 0.5 grams (7½ grains), and the effective dose is usually one or two tablets three or four times a day (total of 1.5 to 4.0 grams daily) depending on the size of the patient. The drug can be given in these doses for long periods without producing any toxic reaction, but, when larger doses are used, one should watch for the development of acidosis. If enteric-coated preparations are given, nausea and vomiting can usually be avoided. To be sure that the dose is effective, the pH of the urine should be checked occasionally with nitrazine paper.

Mercurial Diuretics

These substances are organic compounds of mercury. Some of the better known preparations for intravenous and intramuscular injection are mercuzanthin, mercuhydrin, and salyrgan with theophyllin. These are obtainable in 1 c.c. and 2 c.c. glass ampules. For rectal administration, mercuzan and salyrgan with theophyllin are available as suppositories. Preparations of mercurial diuretics for oral administration have also been introduced recently, but they are not so satisfactory as the other forms since their absorption is uncertain and their administration not infrequently causes nausea, cramps, and diarrhea.

It is customary among physicians to give the mercurials in 1 c.c. or 2 c.c. doses at intervals of once or twice weekly. Even in adults such amounts of these potent diuretics, as a rule, cause a marked increase in urinary output for a period of about twenty-four hours, after which for several days there is a compensatory drop in the

urinary volume to a level somewhat below the usual average. This method of administration, therefore, has the disadvantage of causing considerable fluctuation in kidney excretion. Furthermore, the sharp rise in fluid loss may cause dehydration, chloride depletion, and consequent debility of a high degree.

A somewhat more satisfactory way of administering the mercurial diuretics, a way which has been emphasized only in the past few years, is to give the smallest amount which will produce a rise in urinary output above that of the fluid intake, and to repeat the dose at frequent intervals. In adults it may be possible to obtain a suitable diuresis with as little as 0.25 to 0.5 c.c., and in children 0.10 to 0.25 c.c. may suffice. If an adequate effect can be obtained with such small amounts of the mercurials, it is safe to inject the substance as often as every day or every other day and in this way avoid the marked fluctuations which are produced with the less frequent administration of large doses. Unfortunately, however, it is very difficult in most patients to obtain an absolutely constant and continuous diuresis even by the frequent small dose method.

The intramuscular route for the administration of mercurials is generally preferable since it is less likely to cause serious reactions than the intravenous route and usually causes a satisfactory diuretic response. The rectal route is often suitable for patients who are at home and who do not have the services of a physician or a nurse available at the time the drug is needed. Sometimes prolonged use of suppositories causes considerable rectal irritation so that the suppository can no longer be retained. When rectal suppositories are used for children, sufficiently small doses can be obtained by dividing the suppository longitudinally. The mercurial diuretics must never be given subcutaneously, for even a small amount under the skin may cause marked irritation and severe pain.

As has been already mentioned, the response to the mercurial diuretics may be greater and the minimal effective dose may be smaller if the patient's urine is kept acid by the oral administration of ammonium chloride. The latter may be given for a few days at a time, starting the day before the mercurial is administered, or it may be given as a daily ration for long periods, the mercurial preparation being given intermittently.

Comparison of Mercurial and Theobromine Diuretics

With rheumatic fever patients, mercurials are effective in a somewhat higher percentage and produce a much greater amount of diuresis than the theobromine substances. However, the mercurials, even when given in small amounts at frequent intervals, tend to have an intermittent action, whereas the theobromine drugs cause a more continuous diuresis. The theobromine diuretics also have the advantage of being effective when given by mouth. Because of these differences, the theobromine substances are not likely to be so upsetting to the patient.

In general, for patients in whom the production of diuresis is not of the utmost urgency, it is advisable to give the theobromine diuretics a trial and to continue them as long as they are effective. If the amount of fluid retention is great, and if time is important, or if theobromine diuretics have been tried without success, then it is advisable to use the mercurials. Often, if diuresis can be started by the use of the mercurials, a satisfactory fluid balance can be maintained by shifting to one of the theobromine preparations even though the latter originally had failed to be effective.

Digitalis

When auricular fibrillation is associated with congestive heart failure, digitalis is the drug of choice, and its use may produce dramatic results. The drug may also be of value in the treatment of certain other disturbances of rhythm.

However, when the cardiac rhythm is regular, digitalis usually produces a slight effect or none at all on the heart rate and on congestive failure which is associated with active rheumatic fever. In only occasional instances is the diuretic response great after digitalization. Furthermore, unless considerable caution is used, digitalis may sometimes have serious toxic effects on the heart. For these reasons digitalis is of secondary importance, and diuretics together with salt restriction should be resorted to first in the treatment of congestive failure. Only if the latter regimen fails to produce a satisfactory response should the patient be digitalized, and digitalization must be done cautiously.

Time does not allow for a detailed discussion of methods of administering digitalis, but they are essentially the same as those used when the drug is administered for the treatment of various

kinds of adult heart disease. Either whole leaf preparations or the more recently introduced pure glycosides may be employed. The dose used for children should be calculated on the basis of weight. Because patients with active rheumatic fever seem to be particularly susceptible to the toxic effects of digitalis on the myocardium, the drug should never be "pushed."

After-Care of Rheumatic Heart Disease

In discussing the treatment of rheumatic fever, it was pointed out that once the rheumatic process had completely subsided, gradually increasing physical activity should be allowed. Emphasis was put on the word gradually. Even after the patient is up all day, the continuation of a daily rest period of one to two hours is advisable for another year or longer. Out-of-door walks in good weather and mild forms of exertion favor improvement in muscle tone and should be encouraged. However, during the first year after recovery from an attack of rheumatic fever, the patient should avoid all forms of vigorous physical activity.

A regimen of gradually increasing activity is designed to keep the patient constantly in a well-rested condition and is based on the premise that fatigue induces the lowering of body resistance and hence contributes to the development of respiratory infections and flare-ups of the rheumatic process. The restrictions placed on the patient's activities are not aimed directly at the heart itself, and they are necessary even if the patient has escaped cardiac involvement.

After this first year of restricted physical activity has elapsed, what and how much should the patient be allowed to do? The answer to this question is extremely important. All too often the problem is so handled that many individuals who should be leading normal lives are reduced to a state of chronic invalidism. The physical activity allowed for persons with rheumatic heart disease should depend upon the degree of cardiac damage. The best measures of the latter are the size of the heart and the individual's actual tolerance for physical activity. Heart size is usually a much more accurate indication of the degree of cardiac involvement than are heart murmurs. As a rule, the bigger the heart, the greater is the damage. Tolerance for physical activity is best measured by what the patient finds he can do without becoming short of breath.

Individuals whose hearts are either normal in size or only slightly enlarged, and whose ability to perform exercise without developing shortness of breath is not below normal, should be restricted very little if at all. They should be allowed to take part in various sports such as swimming, golf, tennis, baseball, and even football. Perhaps extremely arduous activities such as long distance running are best avoided. I have known of some excellent performers in various fields of sport who have had mild rheumatic heart disease and whose participation in these sports apparently did not aggravate their cardiac condition. One young man whom I have particularly in mind had slight but definite aortic regurgitation. Nevertheless he was not only captain of a well-known college football team but was even named as a back on the "All-American" team.

When the heart is more than slightly enlarged, and when tolerance for physical exertion is reduced, the patient's physical activities must be limited. Even in these circumstances some mild forms of exercise are permissible. For such individuals the best rule is that as soon as slight dyspnea appears and before extreme fatigue develops, the causative activity should be stopped.

The foregoing discussion is based on the premise that physical exertion within the limits of exercise tolerance does not cause any undue myocardial strain or any increase in valvular damage of the rheumatic heart. Progression in rheumatic heart disease is nearly always due to recurrences of rheumatic fever. In other words, it is the active rheumatic process rather than physical strain which usually makes the heart grow worse. *Therefore the most important aspect of the after-care of patients with rheumatic heart disease, and as a matter of fact for all individuals who have once had rheumatic fever whether or not they have cardiac involvement, is the prevention of rheumatic fever recurrences.* The after-care should also include some attention to the prevention of subacute bacterial endocarditis, a not uncommon and an important complication of rheumatic heart disease.

Prevention of Rheumatic Fever

The prevention of rheumatic fever recurrences constitutes one of the most important aspects of the entire rheumatic fever problem and is fortunately a phase of the problem in which real progress has been made during recent years. As has

already been pointed out in previous discussions, rheumatic fever is a repetitive disease. It tends to return again and again, and with the recurrence more and more heart damage may be produced.

The methods of prevention are chiefly measures aimed at the prevention of hemolytic streptococcal respiratory infections, which are responsible for practically all recurrences of rheumatic fever, and, since streptococcal and nonstreptococcal infections are not always readily differentiated, measures aimed at the prevention of all respiratory infections.

General Measures

Respiratory infections are extremely contagious. Therefore, the rheumatic individual should avoid, as far as possible, exposure to people who have colds and should also avoid chilling and exposure to cold wet weather.

The spread of respiratory infections is especially favored by the herding together of individuals. Since the danger of rheumatic recurrences is particularly great during the first six months to a year after recovery from the disease, it is probably advisable during this period that the rheumatic child does not return to regular school nor attend church, the movies, or other crowded places. While home instruction is being given, the school teacher, social worker, and friends must be warned not to visit the home if they have any likely symptoms of a cold. When the patient finally returns to regular school, the co-operation of the school teacher should be requested in an attempt to prevent the child from sitting next to others who have respiratory infections.

The rheumatic child should sleep by himself in his own room, for sleeping with others is conducive to the contraction of colds.

"Body resistance" should be kept at its optimum by providing a well-balanced diet, plenty of sleep, and an extra rest period during the day.

Sulfonamides

It has been pointed out previously that the sulfonamide drugs not only are of no value in the treatment of rheumatic fever but that they may actually aggravate the active rheumatic process. Furthermore, even if streptococcal respiratory infections are treated with sulfonamides as soon as they are detected, there is no evidence that the therapy will decrease the incidence of rheumatic recrudescences. However, information has accumulated which suggests that the daily administration of small amounts of sulfonamide drugs to patients who have fully recovered from an attack of rheumatic fever will protect these individuals in large measure against the development of hemolytic streptococcal respiratory infections and hence prevent further attacks of rheumatic fever. Rosenberg and Hench gathered together the data of seventeen reports in the medical literature between 1939 and 1945 and found that among persons receiving sulfonamides the rheumatic fever attack rate was 2.2 per cent (twenty-two definite recurrences in 1,037 person-seasons), whereas the attack rate among untreated controls was 13.7 per cent (183 definite recurrences among 1,340 person-seasons).

When used for this prophylactic purpose, the sulfonamide preparation can be given in small amounts, but the drug must be given every day. Protection is afforded only so long as there is sulfonamide in the blood. The drug is not effective, of course, against sulfonamide-fast strains, but fortunately these are not common. Protection against sulfonamide-susceptible strains is not absolute either, and recrudescences of rheumatic fever have occurred in individuals taking the drug. However, the hazard of hemolytic streptococcal infection and the resultant chances of further rheumatic fever are greatly reduced.

Preparations and Dosage.—Although sulfanilamide and sulfathiazole were used in most of the published studies on rheumatic fever prophylaxis, the more recently introduced and apparently less toxic drugs, sulfadiazine and sulfamerazine, would seem to be preferable. But, with present knowledge, it is still difficult to determine which of these last two preparations is the more suited to the rheumatic fever prevention problem. Each has certain advantages and disadvantages.

The factors influencing the choice of a sulfonamide preparation are the antibacterial activity of the free drug, the height and constancy of the blood level obtained with small infrequent doses, the proportion of the drug which remains unconjugated (nonacetylated), and the amount of the drug which remains unbound to plasma proteins.† Sulfamerazine has the advantage of giving a higher and more constant blood concentration

†Observations by Bernard Davis on the affinity of plasma proteins, particularly albumin, for a wide variety of substances may have an important bearing not only on the problem of chemotherapy but also on many other problems in pharmacology, bacteriology, immunology, and physiology.

of the free (nonacetylated) drug with a given dosage. Hence, the desired level can be attained with smaller amounts and less frequent administrations. On the other hand, sulfadiazine does not become as readily bound to plasma proteins as does sulfamerazine. Reports in the medical literature suggest that at an approximate concentration of 10 mg. of the unconjugated drug per 100 c.c. of plasma, between 60 and 80 per cent of sulfamerazine is bound, while only 30 to 50 per cent of sulfadiazine is bound. Furthermore it appears that protein-bound sulfonamides are lacking in antibacterial activity. This difference would seem to indicate a definite advantage in the use of sulfadiazine. Unfortunately, available information comparing the concentrations of total effective drug (nonacetylated and unbound) in the blood of patients at various time intervals after small doses of these two sulfonamides is lacking, and hence a final decision cannot be made as to which of the two is likely to be most effective for prophylactic purposes.

In spite of a lack of exact information, certain approximations can be made. A careful study by Phair, Schoenbach, and Merrell shows that at various time intervals following single 1-gram and 2-gram doses, the concentrations of nonacetylated drug in the blood, on the average, are twice as high for sulfamerazine as for sulfadiazine. On the other hand, the various studies concerned with the binding of sulfonamides by plasma proteins suggest that for a given concentration of the total nonacetylated drug, the percentage of unbound drug, on the average, is twice as high for sulfadiazine as for sulfamerazine. Hence, it may be concluded that following a given dose the concentration of effective drug (nonacetylated and unbound) at any particular time interval is about the same for sulfadiazine and sulfamerazine.

For prophylactic purposes, the total daily dose of either of these preparations should probably be between 0.5 gram (7½ grains) and 1.0 gram (15 grains), depending upon the size of the patient. The total daily amount can be divided into two doses, one before breakfast and one at bedtime. The blood levels, which probably should be between 1 and 4 mg. per 100 c.c. for sulfadiazine and between 2 and 8 mg. per 100 c.c. for sulfamerazine, can be checked occasionally, and if necessary the dose can be adjusted to obtain the desired level.

Toxic Reactions and Precautionary Measures.—The great majority of individuals can take daily small rations of sulfamerazine or sulfadiazine without difficulty. Nevertheless, the sulfonamide drugs are potentially toxic substances, even when given in small doses, and may cause renal irritation, agranulocytosis, anemia, rash, and fever. Sometimes the toxic effects can be quite serious, especially if they are not recognized and are allowed to continue. Indeed, the danger of toxic reactions is sufficiently great so that sulfonamides should never be administered over a period of a week or longer to any patient unless both the physician and the patient are prepared to have both clinical examinations and appropriate laboratory tests at adequate intervals.

The longer an individual takes sulfonamides without difficulty, the less are the chances of his subsequently developing an untoward reaction. Examinations and tests, therefore, must be made more frequently at first and less frequently as time goes on. However, since even very late toxic reactions have sometimes occurred, the check-up observations should never be dispensed with altogether. An apparently satisfactory routine is as follows: Check-ups are made twice weekly for the first two weeks, once weekly for the next two weeks, and then every two weeks until a total of three months has elapsed. The examinations may then be spaced at four to six week intervals until the end of the first year. Thereafter, as long as the sulfonamide regimen is continued, the patient should be seen every two or three months.

At each visit a urine should be tested for albumin and its sediment examined under the microscope for the presence of red blood cells, and blood should be taken for a hemoglobin determination and a leukocyte count. A differential count is necessary only if the total white blood cell count is under 5,000.

The appearance of any definite toxic manifestation is, of course, an indication for the immediate discontinuance of sufonamide drugs.

Indications for and Duration of Prophylactic Sulfonamides.—The danger of recurrent rheumatic fever is so great that all children who have recovered from definite or probable rheumatic fever, irrespective of whether heart damage has been sustained, should be protected with daily small doses of sulfonamides—provided that ade-

quate check-up examinations and tests can be made and provided that no toxic reactions develop. Because of the frequent visits to the physician's office and the frequent blood tests necessitated by the prophylactic regimen and because of the risk of toxic reactions, sulfonamides should not be used unless the diagnosis of rheumatic fever has been reasonably certain.

Although the risk of recurrent rheumatic fever exists at all times, in civilian life it probably is considerably reduced after adulthood is reached. That there is a greater risk during childhood may be partly explained by the fact that exposure to hemolytic streptococcal infections is greatest during the period when children are herded together in schoolrooms. Therefore it is advisable that the prophylactic sulfonamide regimen be continued until the age of twenty years or at least until the completion of school.

Although hemolytic streptococcal infections decrease in frequency during the summer months, they do not disappear completely during this period. It is probably advisable, therefore, to administer sulfonamides throughout the year rather than to discontinue the drug during the summer months. Moreover, the temporary omission of therapy does not decrease the risk of toxic reactions nor does it appreciably reduce the number of necessary check-up examinations.

Penicillin

Penicillin, like the sulfonamides, has no therapeutic virtues once active rheumatic fever has begun. However, preliminary observations suggest that this antibiotic may have some application to the prevention of rheumatic fever recurrences. For purposes of prevention, penicillin might be used in two ways. The first is its use in therapeutic doses for the treatment of hemolytic streptococcal respiratory infections. The second application is for the prevention of streptococcal infections by the daily administration of an oral preparation of the drug.

Treatment of Hemolytic Streptococcal Infections.—The use of penicillin in this connection is still experimental. Nevertheless there is reason to believe that the prompt treatment of hemolytic streptococcal respiratory infections with penicillin in adequate doses may considerably reduce the chances of subsequent rheumatic fever recurrences, which normally occur in about 50 per cent of instances. The observations on which this statement is based are as follows:

1. Penicillin, *in vitro,* has a marked bactericidal action on most strains of hemolytic streptococci.

2. Throat cultures of patients ill with hemolytic streptococcal infections become "negative" very quickly after adequate penicillin treatment is started, and if the treatment is continued for ten days, the throats of most patients can be permanently cleared of hemolytic streptococci. This finding is in contrast to the effect of sulfonamides which as a rule take longer to produce "negative" cultures and which usually do not permanently clear the throat of streptococci.

3. If hemolytic streptococcal respiratory infections are treated with penicillin within twenty-four hours of onset, the causative organisms are killed so quickly that streptococcal antibodies (such as the antistreptolysin titer) sometimes fail to develop in the serum. Such results are not generally obtained when sulfonamides are used as the therapeutic agent.

When penicillin is used in an attempt to prevent rheumatic fever recurrences, treatment should be started as soon as possible and should be used for all respiratory infections with which there is a red sore throat or definite fever. Whenever possible a throat culture should be taken just prior to starting therapy, but the initiation of the treatment should not be postponed until the results of the culture are known. If after one or two days the culture is reported as "negative," the penicillin therapy can be discontinued; but if the culture is found to be "positive" for hemolytic streptococci, the treatment should be continued for a total of ten days even though apparent clinical recovery may occur much sooner than this. For adequate penicillin therapy, either 25,000 units of the antibiotic should be given in saline or distilled water intramuscularly every three hours day and night, or 300,000 units of calcium penicillin in beeswax and oil should be administered intramuscularly once daily, or 200,000 units should be administered by mouth five times daily. As soon as the temperature has reached normal and clinical recovery from the respiratory infection has occurred, therapy may be continued with oral penicillin, 100,000 to 200,000 units three or four times daily.

It should be pointed out that the rationale on which this application of penicillin is based is

chiefly theoretical. The number of actual observations of rheumatic individuals who have had hemolytic streptococcal infections treated with penicillin is not yet sufficient to tell us just how much, if any, the incidence of rheumatic fever recurrence is reduced. Nevertheless, since penicillin therapy is essentially a harmless procedure, it would seem advisable to use it for all respiratory infections of possible hemolytic streptococcal etiology among rheumatic fever susceptible individuals.

Penicillin therapy of streptococcal respiratory infections should be used not only for individuals who have recovered from previous rheumatic fever but also for those who are ill at the time with an active rheumatic process.

Prevention of Hemolytic Streptococcal Infections.—If penicillin is to be used for the prevention of hemolytic streptococcal respiratory infections, a method of administration must be available which is practical as well as effective. Except during periods of limited duration, the parenteral administration of penicillin obviously is not practical. The antibiotic could not be given this way every day for several years or longer.

When penicillin is given by mouth in doses of 100,000 units to 200,000 units three times daily to individuals who are carriers of hemolytic streptococci, it will usually clear the throats of the organisms, provided care is taken to give the drug at least one hour before and at least two hours after the ingestion of food. Although the clearing is not permanent in some instances, most individuals will have negative throat cultures for hemolytic streptococci as long as penicillin is being administered.

From these observations it is reasonable to conclude that the oral administration of 100,000 to 200,000 units of penicillin three times daily will also prevent the implantation of most strains of hemolytic streptococci in the throats of individuals taking the drug. Obviously this method of preventing streptococcal infections could be expected to be effective only as long as the antibiotic is being taken, and obviously the cost of oral penicillin would make its long-time administration prohibitive for most individuals. However, since in time the cost of penicillin may be sufficiently reduced to allow for its use, or the effectiveness of oral preparations may be improved so that smaller daily doses can be used, space has been given here to this possible way of preventing rheumatic fever. The relative safety of penicillin gives it a decided advantage over the potentially toxic sulfonamides, but until penicillin becomes more readily available, the daily administration of small doses of sulfadiazine or sulfamerazine will continue to be the method of choice for the prevention of rheumatic fever recurrences.

Transportation to Low Incidence Areas

Although information regarding the geographic distribution of rheumatic fever is still far from adequate, the available data suggest that the disease is less prevalent in tropical and subtropical areas than in the more temperate zones. Variations in geographic distribution of rheumatic fever are probably related to variations in the incidence of hemolytic streptococcal infections, but more exact information is still needed regarding this relationship.

There is no reason to believe that living in a southern climate will have any influence on the course of an attack of rheumatic fever once the active process has been established. On the other hand, if patients who have recovered from rheumatic fever and who live in relatively high incidence areas are transported to geographic areas of low incidence, the chances of subsequent recurrences will be reduced. It is obvious, however, that if transportation is to have any lasting beneficial effect, the patient must remain permanently in the low incidence area.

Salicylates

Observations reported by several different investigators suggest that if salicylates are administered promptly at the time of respiratory infections and continued for one month, the incidence of rheumatic fever recurrences is reduced. The daily dose of salicylates when used for this purpose is not large and averages between 0.03 gram (½ grain) and 0.045 gram (¾ grain) per pound of body weight. The total daily amount is administered in divided doses during the day only. Aspirin, sodium salicylate, or other forms of salicylate can be used.

On the other hand, the value of salicylates for the prevention of rheumatic fever is questioned by some physicians who believe that the drug by its effect on fever and pains merely camouflages the disease so that its presence is unrecognized. It would appear that the last word regarding the

prophylactic virtues of salicylates, just as in the case of the drugs' therapeutic virtues, has not been said and must await further studies.

If one wishes to give moderate doses of salicylates at the time of respiratory infection with the hope of possibly preventing rheumatic fever, there certainly can be no real objection, provided one is also alert to the possible masking effect of the drug. However, the procedure should not be substituted for the prompt treatment of respiratory infections with penicillin, a preventive measure which holds more promise of being effective. If salicylates are given, they should be used in addition to penicillin.

Prevention of Bacterial Endocarditis

Next to recurrent rheumatic fever, bacterial endocarditis is one of the most feared complications for the individual with a rheumatic heart. Prior to the discovery of penicillin, it was an almost invariably fatal disease. Although it rarely appears when the heart is entirely normal, it can occur on valves which are only slightly scarred as well as in hearts that are more severely damaged.

It is known that bacterial endocarditis is due to the direct invasion of the blood stream by bacteria which then lodge and grow on the heart valves, but the cause for the bacterial invasions is not always evident. In some instances it is due to a respiratory infection; while in others it is due to the temporary opening up of small blood vessels in vascular areas such as at the time of tonsillectomy or tooth extractions. Even such simple processes as the vigorous cleaning of teeth and the scraping of tartar off teeth at the gingival margins have been known to be followed by subacute bacterial endocarditis.

Bacterial endocarditis cannot always be prevented, but there is reason to believe that its incidence can be reduced by the following precautionary measures.

1. All severe respiratory infections should be treated with effective doses of penicillin.

2. Penicillin should be administered at the time of tonsillectomy, other operations, and at childbirth. Therapy should be started if possible the day before the procedure and continued for several days after it.

3. Sulfadiazine should be given at the time of tooth extractions and other dental work which involves manipulation of the gingival margins of the gums. For these purposes the drug should be started twelve to twenty-four hours before the procedure and continued for a total of four days. A suggested dose of sulfadiazine is 1 gram (15 grains) three times daily. If the patient happens to be in the hospital, it is advisable to substitute penicillin therapy for the sulfadiazine because it probably is somewhat more effective. Similarly, when tooth extractions are necessary for individuals who have or have recently had rheumatic fever, it is safer to use penicillin than sulfonamides.

FIRST EXAMINATIONS OF "PRIME OF LIFE" GROUP COMPLETED IN HEART DISEASE STUDY

Completion of the first annual physical examinations and tests of more than 300 Saint Paul and Minneapolis men between the ages of forty-five and fifty-four, who are serving as volunteer "human guinea pigs" in the long-range cardiovascular disease study being conducted at the University of Minnesota, was reported in April by Dr. Ancel Keys, director of the University's laboratory of physiological hygiene.

Subjects in this age bracket taking part in the research project are designated as the "prime of life" group. Tests on some 200 young men, eighteen to twenty-five, were completed last fall.

Sponsored in part by the United States Public Health Service, the heart disease study is designed to discover the individual characteristics and personal habits which affect the development of arteriosclerosis and hypertension. Most important phase of the program is the yearly testing of a carefully selected group of men who were free of these diseases when first examined.

Insurance records, according to Dr. Keys, predict that half of these men will die of diseases of the heart and blood vessels. The project under way in the Minnesota physiological hygiene laboratory seeks to find out the "how" and "why" of this present gloomy picture. Eventually it is hoped that it will be possible to predict the danger faced by each individual and to adjust his manner of living so as to delay or prevent the heart disease which now kills approximately half of all adults in the United States.

From among 1,000 men who applied for the project, 311 were selected for the "prime of life" group. First condition for acceptance was that the subjects be in general good health and free from significant cardiovascular disease. However, tests and measurements made in the laboratory showed that many of the subjects selected were less healthy than had been supposed.

Of the 311 men chosen for the elder group, nine had abnormalities which required that they be dropped from the program, and at least ninety others were found to have already developed some abnormalities of the heart and blood vessels.

Some degree of hypertension was discovered in forty-four of these ninety men, and forty-six had abnormal electrocardiograms, fourteen of the group being abnormal in both respects.

ABDOMINAL HODGKIN'S DISEASE

With Report of a Case Involving Retroperitoneal Nodes

W. O. B. NELSON, M.D., and L. A. DWINNELL, M.D.
Fergus Falls, Minnesota

HODGKIN'S disease has various synonyms such as lymphogranuloma, pseudoleukemia, malignant granuloma, Sternberg's disease, Hodgkin's granuloma, Hodgkin's sarcoma, and sarcomatous Hodgkin's disease.

Isaacs[11] presents some interesting figures for this clinical entity and states there are less than 2,000 deaths per year (average for the years 1934-1936 was 1,614) in the United States from this cause. The rate has increased slowly. In 1921, the rate was 0.6 per 100,000 for white men, and 0.3 per 100,000 for white women. In 1931, it was 1.5 per 100,000 for white men, and 1.0 per 100,000 for white women. Thus the disease is generally accepted as being two to three times as great in men as in women. The percentage distribution of deaths in 1936 is also interesting: 7.34 per cent were under fifteen years; 40.52 per cent were in the age group from fifteen to forty-four years; 34.87 per cent were in the forty-five to sixty-four age group, and 17.27 per cent were over sixty-five years of age. Goldman and Victor[8] state that the youngest patient with Hodgkin's disease in their experience was five years of age, and the oldest was seventy-six years, with the highest incidence in the third and fourth decades. From these statistics, it is seen that one must be on the alert to diagnose this perplexing disease from childhood to senility.

No positive etiological factor has yet been determined. Ewing[7] cites several authorities who have found Hodgkin's disease to be closely allied to the acid-fast bacillus of tuberculosis. Others,[9] working with fresh tissues surgically removed from patients with Hodgkin's disease and inoculated into chickens, guinea pigs and rabbits, have been unable to prove the tuberculosis theory, and in their series no tubercle bacilli were found except in the case of proven tuberculosis. Bell[1] states that there are two views, the infectious and neoplastic, and that supporting the infectious theory is the febrile course and the presence of several cell types, and that in favor of the neoplastic is the 100 per cent mortality and the difficulty of distinguishing Hodgkin's disease from lymphosarcoma which is an admitted neoplasm. Busman and Johnson[2] state that the disease should be considered a malignant neoplasm since there is no uniformity in its symptom complex.

Ziegler's[15] classification is as follows:

1. Localized type.
2. Generalized type.
3. Mediastinal type.
4. Larvae or typhoidal type.
5. Splenic type.
6. Osteitic type.
7. Acute type.
8. Other types.

When one ordinarily thinks of Hodgkin's disease, one thinks of cervical adenopathy with easily palpable nodes and even a collar-like appearance of the enlarged glands in the neck. Desjardins[5] states that "Hodgkin's disease may start in any lymph nodes or agglomeration of lymphoid tissue in the body. Such as a node under the serosa of the gastric wall, a Peyer patch or lymph follicle in the small intestine, or in the lymphoid tissue of the vermiform appendix." But from a practical standpoint, he adds, these conditions start most frequently in the para-aortic nodes. Because the nodes which constitute this group drain the lymph from all the large and important organs in the abdomen, they are the most important group of lymph nodes in the body. Anatomically considered, they are extraperitoneal, or, as they are usually called, "retroperitoneal." Desjardins further states[8] that the enlargement of the retroperitoneal nodes as the earliest manifestation of the disease is much more common than is generally realized; 5 to 10 per cent of the cases of Hodgkin's disease begin in the retroperitoneal nodes.[1]

The symptoms of the involvement of the retroperitoneal nodes consist of diarrhea or constipation, progressive weakness, loss of weight and strength, anemia, abdominal pain, jaundice, ascites, frequently intense generalized pruritis, and a fever which may be persistent or intermittent. Cecil[4] states that in the abdominal form of Hodgkin's disease some of the most pronounced

From the Fergus Falls Clinic, Fergus Falls, Minnesota. Read at the annual meeting of the Northern Minnesota Medical Association, Brainerd, Minnesota, September 6, 1947.

types of remittent fever are seen. Frequently, these patients begin by complaining of loss of strength, loss of "pep," belching and a heavy feeling in the epigastrium, which gradually progress toward the other symptoms, such as increasing difficulty with eating, increasing tendency to constipation, increasing weakness and pruritis which may become almost unbearable. Thus the signs and symptoms are very variable and progressive. It should be re-emphasized that 5 to 10 per cent of all Hodgkin's disease starts in the retroperitoneal nodes, and that in the years 1934 to 1936 there were 1,614 reportable deaths each year from Hodgkin's disease, which would mean that from 80 to 161 of these started in the retroperitoneal nodes. This figure is not high considering the United States as a whole, but one must realize that there are thousands of deaths each year which are listed as due to senility or cardiac failure, without an autopsy being performed. One never knows when one of these rare diseases may be encountered.

One must bear in mind that at times the retroperitoneal nodes become so large that they displace the liver and spleen; that they may enlarge posteriorly and cause pressure symptoms on the lower thoracic vertebra or may even infiltrate through the intervertebral spaces and invade the spinal cord; and that if lower abdominal nodes are involved, pelvic symptoms may develop, and sometimes one may find erosion of the wing of the ilium or symptoms of pressure on the ureters, bladder or rectum.

Therefore, if one sees a patient with a temperature of the Pel-Ebstein type, with pruritis and other abdominal symptoms, with persistent negative Widal tests and negative blood cultures, one must think of Hodgkin's disease involving the retroperitoneal nodes. In some of these cases, of course, the superficial nodes eventually become enlarged, and then an accurate diagnosis may be made by biopsy and examination by a competent pathologist. The diagnosis of this type of Hodgkin's disease is not easy, even with all the numerous present-day laboratory procedures, and it is usually made at laparotomy or at autopsy, and then not grossly but microscopically.

The blood picture is not diagnostic since some of these patients show a leukocytosis while others show a leukopenia. A mild secondary anemia is usually found. Differential blood studies frequently show "toxic changes," with polymorphonuclear shift to the right with marked toxic granulation. Eosinophilia is present in about 5 per cent of the cases of Hodgkin's disease.[12] About 60 per cent show Dorothy Reed or Sternberg cells. It is only by biopsy that a correct diagnosis can be made.

The duration of the disease may be from several months to years. Therefore, if one is fortunate enough to make a diagnosis, the end results are still not very encouraging.

Treatment consists of x-ray therapy and general supportive measures.

Desjardins[5] states that for effective treatment it is important to recognize the different types of involvement that might be found, and to arrange treatment accordingly.

In irradiation, it is well to divide the abdomen in different fields, with the umbilicus as the starting point, using at least four fields. Then the rays in these fields should be conveyed toward the midline where most of the nodes are situated.

The posterior aspect must also be considered, and it should also be divided into four fields and similarly irradiated.

In women who are still menstruating, it is well to avoid irradiation of the pelvis and thus induce artificial menopause unless the iliac nodes are involved. If marked leukopenia exists, or when the general condition does not warrant giving massive doses, it is well to give smaller doses until conditions have improved sufficiently to give larger ones.

In these cases, the doses should be repeated every four weeks up to the point of tolerance.

The technical aspects of x-ray therapy are left to the radiologist. It should not be assumed that x-ray therapy will cure these patients, but it may give them a few added weeks or months of relief from their symptoms and a few added weeks of life.

In very severe cases in which symptoms do not respond to irradiation therapy, Methyl-Bis Compound may be tried. It has been found[14] that this will cause some amelioration of the symptoms, but a cure cannot be expected. The therapeutic use of radioactive phosphorus in the treatment of eleven selected patients with Hodgkin's disease did not prove of therapeutic value in the dosage used.[10]

For the severe pruritis, roentgen ray therapy may be given.[11] Blood transfusions should be given when needed. Vitamins may be of some

value. Hematinics should be given for the usual secondary anemia. A nourishing diet is essential. An attempt should be made to maintain the fluid and electrolyte balance.

We would like to report a case of Hodgkin's disease involving the retroperitoneal nodes without affecting the abdominal organs.

Case Report

The case is that of a seventy-four-year-old white man who was first seen as an outpatient at the clinic in March, 1944. He was treated for a nonproductive cough, which responded well to treatment. At that time his blood pressure was 110/80, and his physical examination was otherwise essentially negative.

He returned to the clinic on September 3, 1946. He stated that he had been well until two to three weeks previously when he first noted anorexia and constipation. For the past few days he had noticed mild generalized itching. Chest and gastrointestinal x-rays were negative. He was treated with colloidal baths and similar treatment without benefit, and was admitted to the hospital on September 20. At that time his blood pressure was 100/76. Except for excoriations from scratching, physical examination was negative.

His urine on admission showed the specific gravity to be 1.009; there was a trace of albumin present, and there were 150 to 200 pus cells and 8 to 10 red cells present. His hemoglobin was 28 per cent; the white blood cell count was 8,950. A differential count showed toxic granulation of the cells, but was otherwise within normal limits. The blood was Rh positive.

After considerable difficulty in obtaining a compatable donor, a transfusion of blood was given. He was treated with increasing doses of ultra-violet light, colloidal baths and ferrated liver. On the sixth hospital day his temperature rose as high as 102.6°. Physical examination was negative. The red cells had almost disappeared from his urine; the number of white cells had reduced to 8 to 10 per high power field. A chest X-ray taken at this time was negative. Sulfathiazole was given empirically. His temperature gradually became normal in forty-eight hours, and the sulfa was discontinued. His general condition improved, and he was discharged from the hospital ten days after admission. At that time his hemoglobin had risen to 46 per cent; the red blood cell count was 3,540,000. His itching was controlled.

He was readmitted to the hospital on October 7 for a blood transfusion.

He was last admitted to the hospital on November 16, 1946. He had become acutely ill at home with severe chills and fever. He had noted generalized weakness for the past few days. The severe generalized itching had returned. Examination showed a tall thin white man who appeared acutely ill. There was a generalized exfoliative type of dermatitis. His blood pressure was 104/60; the temperature was 102°, the pulse 100, and the respirations 24. The examination was otherwise negative.

Laboratory examination on admission showed the urine to contain a trace of albumin and 40 to 50 white blood cells per high power field. The hemoglobin was 56 per cent and white cell count 15,750. A galactose tolerance test and a bromsulphalein test were normal. Repeat chest and gastrointestinal tract x-rays were negative.

The patient became progressively weaker, followed a downhill course in spite of repeated blood transfusions, and expired on December 2, 1946, seventeen days after his last admission and approximately 110 days after the onset of his symptoms.

On postmortem examination the external appearance showed a slight bronzing of the skin. The chest contents were within normal limits save for arteriosclerosis of the aorta. There was a large firm irregular mass in the left abdominal fossa which was retroperitoneal. The distal one-third of the transverse colon and the proximal one-half of the descending colon were firmly bound down to it. A few loops of small bowel were also adherent to the mass, but there was no evidence of encroachment of the lumen. The mass incorporated the aorta and vena cava. It measured 18 by 12 cm. The perivertebral, aortic, pancreatic, and mesenteric lymph nodes were enlarged and firm, but were discrete. The left kidney and adrenal could not be identified as such. The ureter was found to be emerging from the mass. It was markedly thickened and indurated throughout its course to the brim of the pelvis; beyond that point it was normal. On section, the cut edge everted, and the cut surface was seen to contain many small areas filled with thick semi-liquid purulent material. The bladder was markedly trabeculated, and in the vicinity of the left ureter there were three small diverticula, the largest of which contained approximately 30 c.c. of urine. There was a small median bar on the posterior lip of the urethral orifice which apparently accounted for the condition of the bladder and of the urine. The right kidney contained a few small cysts, but was otherwise normal in appearance. The lymph nodes of the pelvis and epigastric area were normal. The spleen and liver showed no evidence of tumor.

A diagnosis of Hodgkin's disease was made from the microscopic sections. They were sent to Dr. E. T. Bell at the University of Minnesota, who confirmed the diagnosis.

Sections of the remaining organs failed to show evidence of Hodgkin's infiltration. Additional diagnoses were arteriosclerosis of the kidney, and fatty infiltration and cloudy swelling of the liver.

Discussion

Fever is an important and significant symptom. The remittant type of Pel-Ebstein is the most important. In our case such episodes occurred. It is important to point out that, contrary to popular opinion, this type of fever is seen in cases other than Hodgkin's disease, notably in patients with caseous tuberculosis and necrotic tumors. Some authors[3] state that it should be "regarded with alarm and frequently indicates that the disease is advancing rapidly." Others[5] state that in cases

"known to have Hodgkin's disease, fever or itching, or both, mean that the condition has involved the retroperitoneal nodes." It is evident that the differential diagnosis of any case presenting idiopathic fever or itching must include Hodgkin's disease, more specifically Hodgkin's disease of the retroperitoneal nodes.

Laboratory findings are usually not significant. An increase in eosinophils is constant enough to be of significance. In some cases it may be as high as 60 per cent. A secondary type of anemia usually develops.

The disease may remain localized as in the case we have presented, but it usually extends along the spine. It may invade the intervertebral foramina; herpes zoster is a frequent symptom of this complication. The spleen, liver, lungs, bone marrow, and superficial lymph nodes are usually involved, frequently in that order.

On gross examination the nodes may strongly suggest neoplasm. They are enlarged, firm, pale, and tend to remain discrete. Microscopically the picture is quite variable, in the same case as well as in different cases. Hodgkin's disease is a disease involving the reticulo-endothelial system. In early infiltration and at the periphery of an involved group of nodes, the picture is frequently that of simple hyperplastic lymphadenitis. The normal landmarks are soon wiped out by the reticulum which is the result of an overgrowth of the lymphoid tissue stroma. This change is prominent early, and is the important diagnostic feature. Lymphocytes tend to become less prominent with the ingrowth of other cells types. A few plasma cells are almost always present. They may be so prominent as to overshadow the other cell types. Eosinophylic cells are usually numerous, but may be entirely absent. The giant (Dorothy Reed) cells are large cells with pale staining cytoplasm and vesicular nuclei. The cell is frequently multinucleated or has a multilobed nucleus. The nuclear membrane stains deeply, and the nucleus contains much chromatin. These cells tend to be more numerous in early lesions.

In old bulky lesions, and in febrile lesions, necrosis may be a prominent feature. This may be followed by extensive fibrosis. These fibrotic bands may comprise the bulk of the tumor.

The microscopic picture may resemble leukemia or lymphosarcoma so closely that diagnosis is impossible. This may be true of biopsy specimens or of specimens obtained at autopsy. In such cases the clinician must be content with a diagnosis of malignant lymphoblastoma. The finer diagnosis is not of importance, as the prognosis and treatment are the same.

Conclusions

1. Although Hodgkin's disease of the abdomen is not a common entity, it is probably more frequent than has been suspected.

2. Hodgkin's disease of the abdomen must be included in the differential diagnosis of any patient presenting idiopathic fever and itching, or other bizarre abdominal symptoms.

3. The positive diagnosis of Hodgkin's disease usually requires microscopic examination of biopsy material.

4. Deep x-ray therapy is the treatment of choice. Added months or years of comfortable life justify intensive treatment.

CLINICAL SIGNIFICANCE OF GROSS HEMATURIA

LAURENCE F. GREENE. M.D.
Rochester, Minnesota

GROSS hematuria usually evokes one of two responses in both patient and physician. The more intelligent patient becomes duly alarmed and promptly consults his physician. The less fortunate patient will pay scant heed to this symptom or will disregard it entirely; the intermittent appearance of blood in the urine will lull this patient into a false sense of security. He will seek medical aid only when the hematuria has persisted for several years and at a time when it is difficult or impossible to cure.

Physicians likewise respond in one of two manners. The more enlightened or conscientious physician will realize that gross hematuria denotes the presence of a pathologic lesion in the urinary tract and that it is his responsibility to determine the source of the blood. To fulfill his responsibility, the physician will either carry out careful and complete urologic investigation or advise that such investigation be made. The less conscientious physician will, without adequate investigation, prescribe tablets or pills, hoping that the hematuria will cease—which it frequently does, only to reappear again.

This consideration will be limited to observations concerning the urologic causes of gross hematuria. This symptom may be produced by a host of medical diseases such as hemorrhagic nephritis, hemophilia and acute leukemia, but a discussion of these conditions is not germane. Of the urologic causes of gross hematuria, malignant lesions and infections of the urinary tract lead the list; these are followed by urinary calculi and prostatism.

It might be enlightening to consider the thoughts and observations of a urologist when confronted with gross hematuria. The age of the patient is important. Gross hematuria is rare during infancy and childhood. When it occurs, it usually is in response to infection, which usually is the result of congenital obstruction in some part of the urinary tract. Thus, a congenital obstruction at the ureteropelvic juncture may produce hydronephrosis which becomes infected and results in gross hematuria. Neoplasms of the urinary tract are uncommon in this age group, and gross hematuria is relatively infrequent. The common malignant tumors of infants, as Wilms' tumor or sarcoma of the bladder or prostate gland, infrequently produce gross hematuria. The former usually is recognized by the detection of an abdominal mass, whereas the latter produces urinary obstruction.

In young adults and persons up to the age of forty, gross hematuria is most commonly a manifestation of infection in the form of pyelonephritis or cystitis. The infection is most commonly produced by organisms belonging to the colon-typhoid or staphylococci groups; tuberculous infections are also common in this age group. Gross hematuria associated with renal or ureteral colic is not uncommon in the presence of renal or ureteral calculi. Neoplasms of the urinary tract are relatively uncommon in this age group.

After the age of forty years, gross hematuria as a result of neoplasms of the kidney, ureter or bladder becomes more frequent. In men of this age group, prostatism, both benign and malignant, is a common cause of hematuria; furthermore, the incidence of gross hematuria is greater in benign prostatic hyperplasia than in prostatic carcinoma. Infection, both specific and nonspecific, and urinary calculi are less common causes of gross hematuria in this age group.

A detailed description of the nature of the hematuria may help to localize the site of the lesion. In males, it should be determined whether the hematuria is initial, terminal, total or independent of micturition. Initial hematuria is characterized by the appearance of blood only at the start of micturition; during the act the urine becomes clear. Initial hematuria is usually produced by prostatism or lesions in the prostatic urethra. In such conditions, blood or blood clots accumulate in the prostatic urethra; when urination is initiated the initial urine is bloody and the remainder clear. In terminal hematuria, clear urine is passed until termination of the act, when the urine become bloody. Terminal hematuria may result from prostatism or lesions in the prostatic urethra; in such instances, the sudden con-

From the Section on Urology, Mayo Clinic, Rochester, Minnesota.
Presented at a meeting of the Dubuque County Medical Society, Dubuque, Iowa, September 9, 1947.

traction of the accessory muscles of micturition is responsible for the terminal hematuria. Rarely vesical neoplasms may be traumatized by the contraction of the bladder and produce terminal hematuria. In total hematuria the urine appears bloody throughout micturition. Total hematuria is usually produced by lesions of the kidney and ureter. The blood enters the bladder and becomes well mixed with the urine. Lesions in the bladder likewise may result in total hematuria. Rarely lesions of the prostatic urethra will bleed into the bladder and result in total hematuria. Bleeding independent of micturition is produced by lesions situated external to the external sphincter.

The color of the hematuria may be of some help in diagnosis. Dark brown urine usually results from bleeding lesions in the upper part of the urinary tract whereas bright red urine is usually associated with lesions in the lower part of the urinary tract. It may be extremely difficult to determine whether bleeding arises from the urinary or genital tract in females; however, careful catheterization and examination of the urine will usually settle the question.

Particular attention should be paid to certain phases of the physical examination of a patient who complains of gross hematuria. Renal enlargement due to neoplasm, hydronephrosis, cyst or polycystic kidney may be detected. Tenderness in the flank, a result of infection, may be elicited. Careful palpation of the supraclavicular area should be carried out because hypernephroma may metastasize to the lymph nodes at that site. The appearance of a left varicocele late in life is suggestive of a neoplasm of the left kidney. This condition is the result of the anatomic relations of the left spermatic vein. Neoplasms of the kidney tend to invade and block the renal vein. Inasmuch as the left spermatic vein empties into the left renal vein, the blockage of the latter vein is transmitted to the spermatic vein and results in varicocele. If the neoplasm invades the inferior vena cava, dilated abdominal veins may be visible.

The suprapubic area should be examined carefully in order to detect the presence of a distended bladder, tenderness that may accompany cystitis, or a mass due to a vesical neoplasm. By means of a careful rectal examination of a man, a diagnosis of benign prostatic hyperplasia or prostatic carcinoma may be made. By rectal palpation it may be impossible to distinguish prostatic carcinoma from tuberculous prostatitis or prostatic calculi, and other diagnostic aids may be necessary. Infiltration of the base of the bladder by vesical neoplasm may be readily detected by rectal palpation.

In cases in which the patients are females, considerable information may be obtained by vaginal examination. In this manner, infiltration caused by vesical neoplasm and tenderness caused by cystitis may be detected. It may even be possible to palpate a calculus low in the ureter by vaginal examination.

Examination of the external genitalia may aid in the diagnosis. The presence of urinary tuberculosis may be suggested by noting evidences of genital tuberculosis, inasmuch as these two conditions are frequently concomitant. Tuberculosis of the vas deferens and epididymis usually results in enlargement, hardening and nodularity of these organs. A urethral neoplasm may be palpable along the course of the urethra.

Every patient complaining of gross hematuria requires complete urologic investigation by a capable urologist. It is axiomatic that in addition to cystoscopy such patients will require investigation of the upper part of the urinary tract, either by intravenous urography or retrograde pyelography. The source of hematuria in a man who has prostatic hyperplasia may indeed be prostatic, but such a patient belongs to the age group in which bleeding may arise from a renal neoplasm.

Hematuria is rarely an emergency unless it is prolonged and exsanguinating in character. Until the time when the patient can be placed in proper hands, there are several steps that may be taken. If it is suspected that the bleeding arises from the kidney or ureter, the patient should be put to rest in bed and necessary narcotics given to relieve pain. A large fluid intake should be urged to prevent the formation of clots and subsequent "clot colic." If the bleeding is vesical or prostatic in origin and associated with the formation of clots, an effort should be made to remove the clots. Clots in the bladder act as a foreign body and produce vesical spasms which aggravate the bleeding. The clots may best be removed by a urethral catheter and syringe.

EXPERIENCES IN THE TREATMENT OF VOLVULUS OF THE SIGMOID

CHARLES E. REA, M.D.
Saint Paul, Minnesota

WHILE volvulus of the sigmoid does not occur very commonly in this part of the country,* the operative mortality rate reported by many clinics is as high as 30 to 60 per cent. As no one seems to have had an extensive surgical experience with this condition, I am offering a review of the literature and my own limited personal experience, with suggestions as to how these cases may be treated to lower this mortality.

Recently Bruusgaard has described a nonoperative method for reduction of the torsioned and distended sigmoid loop by inserting a tube per rectum past the site of torsion of the volvulus. By means of a proctoscope, the examiner notes the condition of the bowel, the appearance of the mucous membrane, and the blood supply at the site of the torsion. When the site of torsion has been located, a lubricated rubber rectal tube, 60 cm. long and about the thickness of a finger (6 to 10 mm. in diameter), is guided past the site of the obstruction. If the treatment is successful, there is a forceful evacuation of flatus and thin stool and the patient feels instant relief. The result may be verified by x-ray examination.

Bruusgaard found the site of torsion of the sigmoid to be 15 to 25 cm. from the anus. After reduction of the volvulus, the tube should be sewed to the anal ring and left for two or three days to prevent recurrence. While there is danger of perforation of the bowel and the possibility that one may fail to operate upon patients with strangulation and gangrene, Bruusgaard reports a mortality of only four in 136 treatments, which makes the above objections seem more apparent than real.

The above procedure would seem to be a valuable one, as experience is gained with it. I have had occasion to use it only two times. In one case, the return of bloody fluid through the inserted tube gave unsuspected evidence of a strangulated volvulus which was verified at operation. In the other case, the patient had a volvulus of the sigmoid together with a carcinoma of the ascending colon just above the cecum. The amount of flatus removed by rectal intubation of the volvulus was not proportionate to the amount of gas seen by a flat plate of the abdomen. The true condition was found at abdominal exploration.

In cases of volvulus of the sigmoid in which there is *no* gangrene or any other severe bowel damage, at the site of torsion, Bruusgaard advises reduction of the volvulus by proctoscopy and intubation, and in a free period of the disease, doing a closed resection of the sigmoid. Wangensteen, at the University of Minnesota Hospitals, has treated two cases of the volvulus of the sigmoid in this manner with successful results. In our experience, however, in the last four cases of volvulus seen, this procedure would have been feasible in only one case, as the blood supply to the volvulus was compromised in three cases.

The usual operative procedure in cases of volvulus has been a bowel resection of the Mikulicz exteriorization type. In my experience, this operation has proved to be a bad one in cases of volvulus of the sigmoid. It is true that one patient (Ancker Hospital, No. 28962) also had Parkinson's disease and another (Ancker Hospital, No. 92058) was elderly, feeble and debilitated, but this high mortality in similar cases has been the experience of others.

Bruusgaard reported five patients with volvulus of the sigmoid treated by exteriorization by the method of Mikulicz; all died. One reason for this mortality is that in cases of volvulus of the sigmoid, the site of the torsion is so distal in the sigmoid flexure that, in doing a Mikulicz resection, there is some risk of producing too much pull in the efferent loop of the sigmoid colon, with resultant gangrene and peritonitis. We have had one case where the efferent loop subsequently retracted into the peritoneal cavity, causing peritonitis and death. To correct this, Bruusgaard recommends that after resection of the gangrenous sigmoid, the distal stump be inverted and buried and the proximal part be brought out as a

(Continued on Page 685)

*In 1946 and 1947, three of the largest hospitals in Saint Paul, Minnesota, record only eight cases of volvulus of the sigmoid: Ancker Hospital (850 beds) seven cases, St. Joseph's Hospital (262 beds) one case, and Miller Hospital (275 beds) no cases.

EXPERIMENTAL STUDIES OF LIVER AND THORACIC DUCT LYMPH

JOHN H. GRINDLAY, M.D., JAMES C. CAIN, M.D., JESSE L. BOLLMAN, M.D., and EUNICE V. FLOCK, PH.D.

Rochester, Minnesota

RELATIVELY few studies have been made of lymph, not because of lack of interest in the subject, but because it has been difficult technically to obtain even small samples of lymph. For example, there is only the most meager information concerning the quantity of lymph coming from a particular organ, such as the liver, or concerning its quantity and composition from a normal animal under conditions such as those following the digestion of a meal.

The object of this study was to investigate hepatic lymph under various experimental conditions. This meant the finding of a method of obtaining a continuous flow of hepatic lymph, a flow that continued even after recovery of the animal from anesthesia. Several difficulties stood in our way: threadlike smallness and delicateness of lymphatics, the almost colorless transparency of liver and lymph and lymphatics, the presence at frequent intervals of valves which interfere with the introduction of a cannula, and the fact that when the lymphatic was punctured it collapsed to the point of invisibility. Moreover, the rate of flow of hepatic lymph is very slow, and the lymph clots rapidly. Our first problems, therefore, were to find a flexible small cannula in which lymph would not readily clot, to develop a technique of cannulation, and to find the proper place to cannulate for hepatic lymph.

The animal used in this study was the dog. Flow of hepatic lymph was measured in thirty-three dogs, twenty-two of which had recovered from anesthesia. Flow of lymph from the thoracic duct was measured in twenty-two dogs after their recovery from anesthesia. The best lymph flow was obtained from young, growing dogs.

The cannula used consisted of a length of capillary size plastic tubing, long enough to be brought out through a stab wound. The tubing was a polyvinyl resin tubing, manufactured under the trade name "transflex" (size 24).* This tubing is not only flexible, but transparent, elastic and smooth-walled. It can be cut easily and may be sterilized by boiling. Transflex tubing of this size is quite inert biologically. Clotting of lymph within the tubing does not readily occur.

After the presenting surface of the lymphatic to be cannulated had been stripped free of overlying tissue, a tiny hole was cut in it. The hole was held open by a fine seeker of blue glass; and the tip of the plastic tube, which was cut on a bevel of about 45 degrees, was introduced beside the seeker into the hole. After the tube was in place, the seeker was withdrawn, and a previously placed ligature was tied about the lymphatic and tubing.

Liver lymphatics emerge from the liver at its hilus and, passing caudally along the free edge of the gastrohepatic ligament, enter a main hepatic lymph node at the caudal end of the foramen of Winslow. These lymphatics are extremely small, thin-walled and numerous, and anastomose with each other freely. Several large efferent lymphatic trunks emerge from the hepatic lymph node and pass dorsally to join the cisterna chyli in the retroperitoneal region. We introduced our cannula through the largest of these efferent lymphatics and occluded the remaining efferent trunks by the mass ligature which held the plastic tube in place. Possible contamination of lymph from the upper part of the duodenum and the pancreas was prevented by one or more mass ligatures around lymphatics entering the hepatic lymph node at its caudal end.

The thoracic duct was usually cannulated behind the descending aorta rather than at the usual site where it empties into the left subclavian vein. Because there are no valves in the thoracic duct, the tubing could in most cases be slipped down the duct until its tip was in the cisterna chyli.

In the trained dogs, hepatic lymph usually flowed for a day and often for as long as two and a half days. Thoracic duct lymph flowed for as long as eight days. The usual flow for the average-sized young dog was 280 c.c. of hepatic lymph and 700 c.c. of thoracic duct lymph for twenty-

This is an abridgment, in part, of a thesis submitted by Dr. Cain to the faculty of the graduate school of the University of Minnesota in partial fulfillment of the requirements for the degree of M.S. in Medicine.

Dr. Cain is a Fellow in Medicine and Drs. Grindlay, Bollman and Flock are with the Division of Experimental Medicine, Mayo Foundation, Rochester, Minnesota.

*The transflex tubing used in this study was furnished by the courtesy of the manufacturer, the Irvington Varnish and Insulator Co., Irvington, New Jersey.

four hours. These dogs lost weight rapidly during the time the lymph fistula remained open and signs of dehydration and hypoproteinemia developed, which in the case of the dogs with fistulas of the thoracic duct were controlled only by constant intravenous reinjection of lymph.

There was evidence that we obtained virtually all the hepatic lymph by the technique of liver lymphatic cannulation. For example, T1824 dye, which had been injected into the several lobes of the liver in several dogs, appeared in hepatic lymph but not in thoracic duct lymph. Also, after the common duct had been obstructed, the bilirubin of hepatic lymph increased rapidly, while bilirubin did not appear in thoracic duct lymph until it appeared in the blood. We believe also that our technique of cannulation of the thoracic duct permits us to obtain almost all the lymph coming from below the diaphragm.

The protein content of hepatic lymph was high as compared to that of thoracic duct lymph. Thoracic duct lymph had a protein content about half that of plasma, while hepatic lymph had a protein content five sixths that of plasma. Our experiments showed that intravenous infusion of fluid, salt and glucose, comparable in volume to that present in the large amount of lymph lost, did not restore dogs to a normal state. Present evidence indicates that a loss of hepatic lymph protein, either from drainage of the liver lymphatics or from drainage of the thoracic duct (into which the liver lymphatics empty), produces loss of weight and weakness.

Hepatic lymph was transparent and had a faintly yellow color. During anesthesia the bilirubin content and depth of yellow color increased. After a meal, thoracic duct lymph became white, and hepatic lymph remained clear. Both liver and thoracic duct lymph contained slightly more glucose and chloride than plasma but the same amount of inorganic phosphate. The alkaline phosphatase content of liver and thoracic duct lymph was about half that of plasma. Exercise increased the flow of hepatic lymph approximately 80 per cent and that of thoracic duct lymph 200 per cent. A meal increased both liver and thoracic duct flow approximately 75 per cent, and intravenous infusion of solution of glucose likewise increased both liver and thoracic duct lymph flow 75 per cent. Two dogs with experimental chronic cirrhosis of the liver had greatly dilated liver lymphatics and an output of hepatic lymph ten to twenty times greater than normal. This and other experimental observations suggest that ascitic fluid may be formed by leakage of hepatic lymph rather than by transudation from tissues of the portal bed. Obstruction of the liver lymphatics was produced on one occasion. Although the biliary tract was unobstructed in this dog, jaundice resulted. This experiment suggests the possibility that jaundice in cases of carcinoma invading the gastrohepatic ligament, in which obstruction of the bile ducts cannot be demonstrated at necropsy, may be caused by carcinomatous blockage of liver lymphatics.

Summary

By using flexible plastic (polyvinyl resin) tubing of small diameter, as cannulas, we have been able to cannulate the extrahepatic liver lymphatics in twenty-two dogs and the thoracic duct in twenty-two dogs and obtain a continuous flow of lymph after the animal had recovered from the operation. Clotting of lymph appears not to occur rapidly in such tubes.

By cannulating the main efferent lymphatic of the liver lymph node and occluding the other efferent lymphatics, we have been able to obtain most of the hepatic lymph. By cannulating the thoracic duct behind the descending thoracic aorta, we usually have been able to slip the plastic tube down to the cisterna chyli and obtain most of the abdominal and hind leg lymph.

The usual flow of hepatic lymph was 280 c.c. for twenty-four hours, of thoracic duct lymph 700 c.c. Severe loss of weight and signs of dehydration and hypoproteinemia developed rapidly. Flow of liver and thoracic duct lymph was increased by exercise, by feeding of a meal and by intravenous infusion of saline or glucose solution.

The protein content of hepatic lymph is about double that of thoracic duct lymph and nearly equal to that of plasma. Chloride and glucose content of both liver and thoracic duct lymph were slightly high as compared to plasma, with inorganic phosphate the same and alkaline phosphatase lower.

Two dogs with chronic experimental cirrhosis of the liver had very large outputs of hepatic lymph.

CLINICAL-PATHOLOGICAL CONFERENCE

DIAGNOSTIC CASE STUDY

E. W. MINTY, M.D., O. L. McHAFFIE, M.D., and A. H. WELLS, M.D.
Duluth, Minnesota

DR. V. J. PACIOTTI: A sixty-three-year-old housewife (Case No. 3218) was admitted to this hospital on September 13, 1945, complaining primarily of vomiting. She expired twenty-one days later. Her present illness appeared to begin two days before admission to the hospital, when she suddenly began vomiting about one hour after her noon meal. There was a moderate chill at the time of the onset. At first there was no pain. She had a bad taste in her mouth. Her bowel movements remained normal, and there was no diarrhea or constipation. The nausea and vomiting continued so that she could not retain anything on her stomach up until the time of her admission. A physical examination revealed a well-nourished, elderly, alert white woman, complaining of vomiting and very little abdominal pain. There was decreased excursion of the right chest as compared with the left, but no râles or areas of consolidation. The heart appeared to be enlarged to the left by 2 or 3 cm.; the rate was 120 per minute, and sounds were rather feeble. There were no murmurs. The apex was felt in the midclavicular line and the sixth intercostal space. The white blood cell count was 15,700, and her blood pressure was 120/80; temperature was 99.2° F., and the urinalysis was normal. There was some tenderness in the mid-abdomen with marked rebound tenderness and no muscular rigidity or abdominal distension.

The past history revealed that the patient had had attacks of right upper quadrant pain over a period of about two years, beginning thirty years ago. These shooting pains went through to her back, and she became quite ill but never consulted a doctor.

The clinical diagnosis was acute appendicitis. The immediately excised appendix was considered by the pathologist to be free from inflammatory change. However, the surgeon felt that it was completely reduplicated upon itself, and the source of some difficulty. At the time of the appendectomy, the gall bladder was found to be obliterated and surrounded by numerous old fibrous adhesions. No stones were found in it, and none could be felt in the common duct. No other pathologic condition was found in the pelvis or abdomen.

Postoperatively, she continued to be distended and vomited small amounts two or three times daily. On September 23 and 25, roentgenograms (Fig. 1) revealed a "stepladder" type of severe distension of the small intestines which were interpreted by Dr. A. L. Abraham as being probably due to intestinal obstruction. She continued vomiting two or three times a day and noticed on occasions some burning pain in the lower abdomen. On September 23, 500 c.c. of liquid fecal matter were vomited. On September 24 she had some mild abdominal pain and was very weak. An x-ray examination revealed some elevation of the right diaphragm. There were large bowel movements described by the nurse. On September 29 she was still vomiting occasionally. On October 1 her temperature rose to 102.8° F. The white blood cell count was 22,000. On October 2, under local and general anesthesia, through the partially eviscerated operative wound, a small loop of ileum was found protruding between the edges of the fascia and muscle. This was returned to the abdominal cavity, and the wound was closed with through and through chromic sutures. There appeared to be an improvement in the next twenty-four hours, but then she rapidly lost strength and expired on October 4.

Fig. 1. "Stepladder" pattern of distension of small intestine.

DR. A. H. WELLS: The case is now open for diagnoses.

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota.

PHYSICIANS: Gallstone ileus. Carcinoma of colon with obstruction. Acute generalized peritonitis with paralytic ileus complicating the appendectomy.

DR. A. H. WELLS: Dr. Moehring is right. The patient did have a gallstone ileus. An oval, finely granular surfaced calculus, measuring 4.5 cm. in one diameter and 3 cm. in the other, was found at the necropsy, tightly wedged in the ileum (Fig. 2) 4 feet above the ileocecal valve. There was, in addition, a pinpoint perforation of the iliac wall 25 cm. proximal to the site of the calculus, and a severe acute generalized peritonitis with 1,000 c.c. of liquid purulent exudate dispersed through the peritoneal cavity. The site of perforation was due to erosion of the calculus through the gut wall possibly on about October 1 when there was a severe rise in

Fig. 2. Gallstone calculus in ileum. Also, a probe is shown passing through cholecysto-jejunostomy fistula.

temperature to 103° F. There was a huge healed cholecysto-duodenal fistula with surrounding dense old fibrous adhesions and mildly distended common and cystic ducts. The only other significant changes were the usual toxic effects of the peritonitis. Dr. Moehring, what led you to the diagnosis?

DR. H. G. MOEHRING: There was a past history of gallstone colic, followed many years later by a sudden attack of intestinal obstruction of unknown etiology, with fecal vomiting and a typical roentgenogram of small intestine obstruction.

Discussion

DR. E. W. MINTY: Gallstone ileus is one of the late and severe complications of cholelithiasis. In spite of the purely mechanical nature of the obstruction, it carries a mortality of from 40 to 50 per cent, thus warranting a better understanding of its nature. I will review briefly some of the pertinent facts relative to a gallstone ileus for your consideration.

Etiology

Gallstone ileus occurs in approximately 2 per cent of all obstructions of the small bowel. Many reports have a very small number of cases, and as it is difficult to determine the exact incidence of gallstone ileus, I think it should be stated that it is probably much more common than we are aware of at the present time. Wakefield, Vickers and Walters[4] in a study of 176 cases of cholecysto-enteric fistulas found only ten cases of ileus; therefore, it is evident that the majority of the gallstones which eroded into the lumen of the bowel were passed through the rectum without causing symptoms. Their conclusions were that the presence of biliary fistulas must be a fairly common condition, and just has not been recognized in the past. As nearly all cases of gallstone ileus are preceded by cholecysto-enteric fistulas, I think it is well that we review briefly the etiology and pathogenesis of this condition before discussing gallstone ileus in detail.

Cholecysto-enteric fistulas are late complications of chronic cholecystitis and cholelithiasis.[2] They may rarely occur secondary to perforation of a duodenal or gastric ulcer, secondary to surgical trauma, and secondary to rupture of an acute cholecystitis with abscess formation and erosion through the duodenum or elsewhere in the bowel. However, the majority of cholecysto-enteric fistulas are between the gall bladder and the duodenum. As this condition is a late complication of chronic cholecystic disease, we would expect to find it in elderly people. Most of the cases reported are in individuals past fifty, with the majority between sixty and seventy years of age, and the incidence seems to be about 4 to 1 for women, as compared to men, which is approximately the same as cholecystic disease. Bear in mind that a cholecysto-enteric fistula has to be present to form a gallstone ileus.

A stone is extruded into the bowel, most likely into the duodenum, passes down the small bowel where it may lodge anywhere, producing an obstruction. A stone up to 2.5 cm. in diameter will probably pass without causing a definite obstruction; however, smaller stones have been known to produce definite bowel obstruction, especially if they have sharp edges which may catch on the lining of the bowel and stop the progress of the stone. The stone may lodge anywhere from the stomach to the rectum, but in the majority of the cases, it lodges in the terminal ileum, as this has the narrowest lumen of any portion of the intestinal tract.

Diagnosis

The text book picture of sudden onset of acute upper intestinal obstruction in a patient, generally an older woman, with a past history of gallstone colic and typical food dyscrasias, should always lead to including calculary ileus in the differential diagnosis. Symptoms of a definite "gall-bladder" attack preceding obstruction occur in approximately 50 per cent of the cases. Some patients may give a history of bowel obstruction or obstipation, which is characteristic of partial obstruction. Complicating the matter is the fact that many elderly people have periods of obstipation due to atonic bowel action and frequently take laxatives for this common complaint. They may or may not have had a previous history of gall-bladder difficulties. Partial obstruction is usually intermittent, and may be present for variable periods of time. There have been cases reported where partial obstruction symptoms were present for over a year before the true diagnosis was made.

The stone may cause a partial obstruction as it progresses, and then it may loosen up and pass on down the bowel, and thus relieve the symptoms, to lodge in a lower portion and produce a partial obstruction there, and the process is repeated until finally the stone reaches the terminal ileum, where it is apt to produce complete bowel obstruction. The chief complaint of these elderly people is that their bowels do not work right. They have a tendency to be partially constipated, and they cannot get their bowels to function properly. They have no distension, very little pain, and as a rule do not appear acutely ill. They may or may not have an elevation in leukocyte count, depending upon the condition of the bowel, as gallstone ileus is purely a mechanical proposition, and since many of them are only partially obstructed, there is very little distension of gas in the proximal ileum.

The biggest factor in making the diagnosis in gallstone ileus is first to suspect it, and second, to rule it out definitely in all elderly people suffering from partial bowel obstruction or definite bowel obstruction. The majority of these patients have been operated upon with a diagnosis of a bowel obstruction without even suspecting or even diagnosing the nature of the obstruction preoperatively, and as most of these people are elderly and in very poor health, the operation results in a fatal termination. In many instances, only at autopsy is the true diagnosis determined. Therefore, any patient who has symptoms suggestive of a partial obstruction should be questioned very carefully relative to any history of chronic gall-bladder disease or of previous gallstone colic. Occasionally a patient will give a history of having passed a gallstone by rectum. If there is such a history, by all means one should think of a gallstone ileus in these cases.

Once the condition is suspected, it can be definitely determined by x-ray, preferably before complete obstruction occurs. Rigler[3] states that all cases can be diagnosed by x-ray study, if the time is taken to work them out. The only accurate method of making such a diagnosis is by x-ray, as the symptomatology and the physical findings of these cases are very misleading and very meager. The diagnosis by x-ray is usually based on the finding of air in the bile ducts, due to cholecysto-enteric fistulae. Sometimes filling of the bile ducts with barium will occur when barium is given by mouth to determine the cause of partial obstruction; however, this sometimes occurs normally with a large patent ampulla of Vater, which allows the barium to go up into the ducts, and unless the fistula is definitely seen, this cannot be relied upon too strongly. Very rarely, pathogenic organisms within the bile ducts and gall bladder will produce air in the bile ducts, but this is so rare that I believe that finding of air outlining the bile ducts is very diagnostic of a cholecysto-enteric fistula. At times an opaque stone may be seen in the small bowel with distension proximal to it. However, as most of these obstructions are of partial nature, the finding of air proximal to the stone is rather unusual. The patient with a known large radiopaque gallstone, whose calculus is not to be seen in the gall-bladder area at the time of onset of symptoms of upper intestinal obstruction, very likely has passed the calculus to the small intestine. At times during a barium enema, the barium will flow into the terminal ileum and definitely outline the stone. Recently, thorium chloride in very dilute solutions has been given by mouth, and in three or four hours it may definitely outline the gallstone in the bowel. Apparently, this does not harm and is not contraindicated, as is barium by mouth, in cases of bowel obstruction. As early diagnosis is imperative for the proper treatment of this condition in these patients with gallstone ileus, it is imperative that first of all the condition be suspected, and secondly, that it be considered in every case in an elderly individual with a history of partial or complete bowel obstruction.

Treatment

The treatment of a gallstone ileus is always surgical. The Wangensteen and Miller Abbott tube, used therapeutically, is definitely contraindicated, except as an adjunct to surgical treatment. In view of the fact that the high mortality is due to inability to make an accurate early diagnosis, and to procrastination on the part of the physician as well as the patient, it is imperative that surgery be instituted as early as possible in these cases. One is justified in some preoperative preparation of the patient, depending entirely upon the patient's condition, but procrastination beyond a few hours is definitely shown in a high mortality rate.

There are three surgical procedures which are followed:

1. One may attempt to milk the stone into the cecum where it will pass by the rectum, which can be done in some instances if the terminal ileum distal to the stone is massaged and dilated as much as possible. Kapel,[1] of Copenhagen, had two such cases and was able to pass the stone into the cecum without opening the small bowel, by meticulously massaging the terminal ileum until it dilated sufficiently for the stone to be pushed into the cecum. He recommends, however, if the stone is not passed by rectum within four days, that it be removed digitally.

2. The procedure most commonly employed is to do an open enterostomy after the stone is moved proximally until normal bowel can be opened over the stone. The bowel is opened with a longitudenal incision, and closed transversally to prevent constriction of the lumen. An enterostomy approximal to the site of operation is sometimes performed.

3. Should the bowel be gangrenous, requiring a resection of that portion of the ileum, this is done and continuity established by a side-to-side anastamosis, as this is considered the much safer type, with or without an enterostomy proximal to the site of anastamosis. If the condition of the patient is critical enough to warrant it, a Mickulitz exteriorization should be done as a life-saving procedure. Before closing the abdomen, the proximal portion of the bowel should be checked for any other stones that may be present, as multiple stones in the intestinal tract are not at all unusual, and, if found, they should be removed. The gall-bladder area should be inspected and the fistula tract examined to see what

the condition of the gall bladder is, and whether or not other stones are present in the gall bladder. As most of these patients are in very poor condition, it is unwise to attack the fistula or the gall bladder at the time of the relief of the obstruction. If an acute cholecystitis exists, a drain should be placed near the gall bladder, so that if a rupture occurs, the abscess can drain outside. As a large percentage of these cases are due to single cholesterol stones, and, therefore, no other stones remain in the gall bladder, the feasibility of taking down the cholecysto-enteric fistula is not indicated and not justifiable, as most of them close spontaneously anyway; however, if multiple facetted stones are present in the gall bladder, a cholecystectomy should be very seriously considered, and done later, preferably before the patient leaves the hospital.

In conclusion, the 40 to 50 per cent mortality in gallstone ileus is due definitely to indefinite symptoms, to procrastination on the part of the patient as well as the doctor, and to the doctor's failure to make an early diagnosis of the condition as it exists. Undoubtedly, the risk involved with the age and condition of the patient also is a very definite factor in this high mortality.

The only thing that can be done in a preventive way is that every individual in whom gallstones have been diagnosed should be definitely advised to have a cholecystectomy done, before reaching the fifth and sixth decades of life, to prevent this and other highly fatal complications from occurring.

Dr. O. L. McHaffie: These cases of gallstone ileus or intestinal obstruction due to the presence of gallstones in the small bowel are of rather infrequent occurrence, to the extent that many surgeons will not have the opportunity of seeing them. However, after having seen a few cases, the surgeon will recognize a rather definite pattern of signs and symptoms. The important features to be remembered are (1) The patients are usually past fifty years of age and have had gallstones over a long period of time, with or without recurrent attacks of cholecystitis and cholelithiasis. (2) There is usually an attack of acute cholecystitis with cholelithiasis during the period that the stone is sloughing through the fistula between the gall bladder and bowel. (3) After the gallstone has sloughed through the bowel, the patient has an interval of relief. The gall bladder drains, and the surgeon is misled into the belief that he is dealing with an acute cholecystitis which is subsiding. Most surgeons prefer to treat these acutely inflamed gall bladders conservatively, and for this reason they are lulled into a false sense of security during this quiet interval, during which time the patient is insidiously developing intestinal obstruction. As in all cases of intestinal obstruction, it is this delay, while symptoms are masked, which leads to error on the part of the surgeon, and to disaster. It is this deceptive quiescent period in these cases which is important and should remind all surgeons, in dealing with a case of acute cholecystitis and cholelithiasis, of the presence of a possible fistula between the gall bladder and bowel with the presence of gallstone ileus.

Conclusions

We have presented the difficult diagnostic case study of a sixty-three-year-old woman who suddenly began vomiting and continued to do so until her death three weeks later. She had a moderate leukocytosis and fever, x-ray evidence of small intestinal obstruction, and a past history of gallstone colic. At the necropsy a large gall-bladder calculus was found blocking the lower ileum. There was a perforation of the ileum proximal to the calculus and an acute generalized peritonitis.

HALF OF PERSONS EXAMINED NEED MEDICAL ATTENTION

More than half of the 419 persons, 219 men and 200 women, who have been examined in the University of Minnesota's new cancer detection center during the first three months of its operation were found to have abnormalities calling for medical attention, Dr. David State, director of the center, reported June 9.

Referred to their personal physicians for treatment after examination at the center were 216 persons, some of whom, according to Dr. State, were suffering from two or even three different conditions requiring medical service.

In examining the 419 men and women who visited the center during March, April and May, University medical specialists discovered nine definite cases of cancer, twenty-seven "suspicious" tumors requiring further diagnosis, ninety-five precancerous lesions or sores, fifty-one benign tumors and eighty-eight nontumorous conditions, such as high blood pressure, requiring immediate attention by a physician.

Doctors assigned to the detection center found that 203 of the 419 persons examined were in good health and not in need of treatment. However, these currently well patrons were advised to return to the center every six months in order to assure themselves that they are still free of cancerous or precancerous conditions.

More than 8,000 applications have been received for admission to the center, and at the present rate at which the center is able to operate, it will require several years to examine all applicants. Anyone who has made an appointment date and who cannot report on the day set is asked to notify the center at least four or five days before the appointed day so that a replacement can be made.

The center is open to men and women of Minnesota in the age bracket in which cancer occurs most frequently, forty-five and over, who are currently without symptoms of cancer. Each person examined is asked to pay a $5 registration fee, but if the patient is unable to meet the charge, he is asked to pay as much of the fee as he can.

Case Report

COR BILOCULARE, TRANSPOSITION OF GREAT ARTERIES, PULMONARY STENOSIS, SITUS INVERSUS, ET CETERA, IN AN ADULT

ROBERT L. NELSON, M.D., and ARTHUR H. WELLS, M.D.
Duluth, Minnesota

IT is calculated that there are approximately 3,000 infants with surgically correctable congenital cardiac defects born every year in the United States. This number, plus a great back-log of children who have not had surgical care, emphasizes the importance of greater interest and knowledge in this special field on the part of the medical profession. Possibly 95 per cent of the surgically treated congenital cardiac anomalies occur as one of three anomalies: patent ductus arteriosus, pulmonary stenosis, and coarctation of the aorta.

Cor biloculare is indeed a rare anomaly,[13] the victims of which seldom survive infancy. Thus far, cardiac surgery appears contraindicated. The frequency of dextrocardia among the patients with these very serious cardiac anomalies is a repeated observation. A confusion of somatic and visceral dissociation in situs inversus is frequent. The variety of the associated anomalies of the heart and its vessels in cases of cor biloculare appears to be almost endless. We wish to add one more case of cor biloculare in an adult to the scanty literature[1-12] on this subject.

Case Report

M. T. was born a "blue baby" in September, 1919, and died on December 4, 1946, at the age of twenty-seven years and three months. On December 6, 1929, one of us (R.L.N.) examined him and made the following notes:

"This ten-year-old boy has been cyanotic all his life. He is of light complexion, but his skin varies from a dusky mottled color at rest to deeply cyanotic on slight exertion. The mucous membranes and the ear lobes remain dusky throughout the daily one-hour periods of bed rest.

"The heart is of the right mid-line type with a diffuse apex beat at the right sternal margin. There is a rough systolic murmur heard over the entire precordium, maximum over the lower sternal area. A distant rushing systolic sound is heard over the base of the heart and is not transmitted along the great vessels of the arch of the aorta. No thrills are palpable. Fluoroscopically, the heart is globular in shape and lies in the right mid chest (Fig. 1). The chambers are not clearly identified. Bronchovascular markings are relatively prominent. An electrocardiogram (Fig. 2) shows inverted P waves in all leads, a right axis trend with Q waves prominent in I and II and small in III. T waves are inverted in I and upright in II and III.

"Diagnosis.—(1) Congenital dextrocardia with complete transposition of the viscera; (2) congenital pulmonary stenosis; (3) congenital interventricular septum defect."

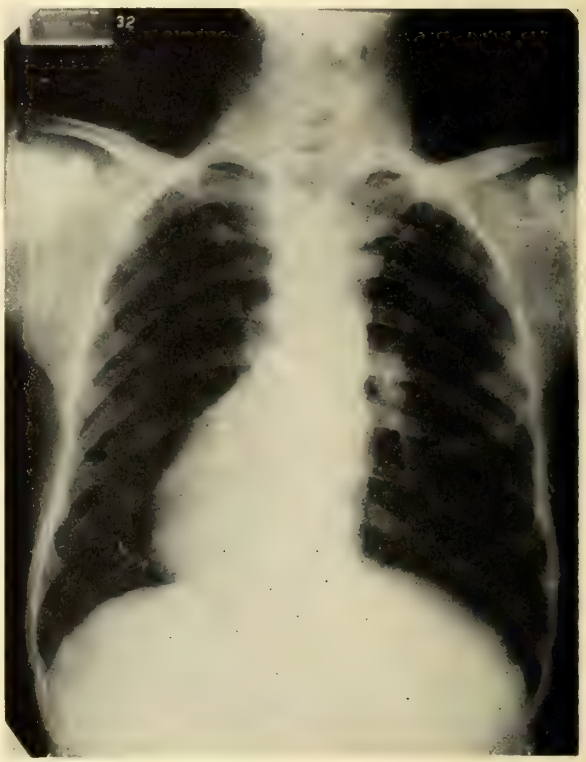

Fig. 1. Thoracic roentgenogram, revealing dextroposition and globular shape of the heart.

During his school years he was allowed all activities which he could tolerate, maintained a good scholastic standing and received special training in art.

When next examined on June 25, 1946, he complained of shortness of breath and painful feet. His feet had been sore since 1939 and empirin compound had ceased to afford relief from pain on walking. Shortness of breath had steadily increased during the past year, causing him to quit a defense plant job at Bridgeport, Connecticut, and return home. He got a job as a commercial artist in a large wholesale house and performed his duties in a satisfactory manner until October 22, 1946, when he developed severe painful edema of both lower extremities.

Examination showed a fairly well-developed and well-proportioned white male who appeared to be about twenty-one years of age (actual age, twenty-six). His ear lobes and all mucous membranes were cyanotic and

From the Departments of Electrocardiography and Pathology, St. Luke's Hospital, Duluth, Minnesota.

there was marked clubbing of the fingers and toes. His height was 68.5 inches (174.5 cm.) and his weight was 128 pounds (58 kg.). The retinal veins were large and deeply purple. The pupils were slightly dilated but reacted normally to light and accommodation. Aside polycythemia. The absence of right axis deviation in the electrocardiograms, however, was confusing. It suggested the equivalent of a right ventricular hypertrophy (left sided because of the dextrocardia) but this could not be corroborated clinically.

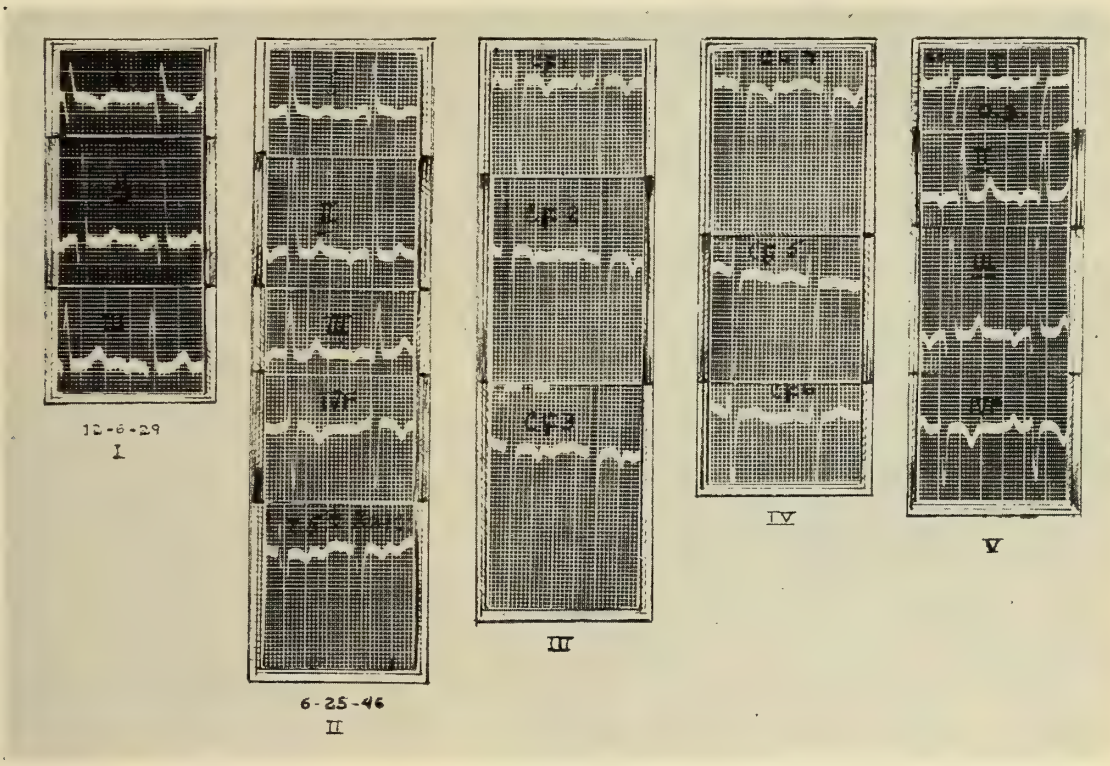

Fig. 2. Electrocardiograms as described in the text.

from moderate postnasal discharge and cyanosis, there was nothing unusual about the rest of the head and neck.

The thorax was rather thin and long. Movement was free and equal, and the lungs were clear. Mediastinal dullness extended 3 cm. to the left and 9 cm. to the right of the midsternal line. The apex beat was diffusely palpable about the fifth right intercostal space. There was a loud, harsh systolic murmur maximum at the second left intercostal space, widely transmitted down to the apex and up to the suprasternal notch and posterior chest, but not along the great vessels of the neck. A coarse thrill was palpable from the first to fourth ribs with maximum intensity at the third rib level at the left sternal margin. Blood pressure was 120/85 in the right arm and 120/90 in the left.

The liver edge was palpable 2 cm. below the left costal margin. The external genitalia were well developed, and the glans penis was moderately cyanotic. There was moderate cyanosis of the lower third of the lower extremities and tenderness over the metatarsal heads of both feet. Reflexes were all physiological.

The urine showed a trace of albumen. Hemoglobin was 19.5 grams. The blood Wassermann test was negative. The electrocardiographic pattern (Fig. 2) was basically unchanged from 1929. In the CF leads, T was inverted in 1, 2, 3 and 4 and slightly upright in 5 and 6. Reversing the right and left arm electrodes and placing the leg electrode on the right leg failed to give a less abnormal pattern, as did reversal of the positions of the chest leads. The diagnostic impression was unchanged from that of 1929 except for the addition of

Clinical Course.—The exertional dyspnea was controlled by pre-exertional ephedrine to the degree that he could walk several blocks instead of half a block without stopping to catch his breath. Digitalis alone was ineffective. More potent analgesics such as codeine and demerol relieved his foot pain for insignificant periods of time, so dehydration with ammonium chloride was tried. This relieved the foot pain but caused diffuse headache, nausea and vomiting, so it had to be discontinued. Mercurial diuretics produced the same effect. He had found that drinking beer also produced headache in from one to six hours and that this persisted in association with nausea and vomiting for thirty-six to forty-eight hours. The headache was not responsive to ergotamine tartrate or histamine but was abolished by inhalation of 100 per cent oxygen.

On October 18, 1946, he complained of severe pain in both ankles and feet. From the lower level of the calf to the level of the malleoli on both legs, the skin was a brilliant red, the area was edematous, and expansile pulsation was present. This was a severe bilateral erythromelalgia of unusual location. A request for study at the University of Minnesota Hospital was granted on November 1, 1946, by which time the erythromelalgia had subsided to a dusky hue and was not pulsatingly painful. It was deemed advisable to make such additional studies as were necessary to determine whether any surgical corrections could be employed. Also, means were to be sought for controlling the increasingly frequent and severe headaches.

Dr. Cecil J. Watson, of the University of Minnesota,

supplied us with a summary of the studies made at the University Hospital. The history and physical findings were essentially as previously outlined.

Examination of the blood revealed 19.3 grams of hemoglobin per 100 cubic centimeters and 8.5 million

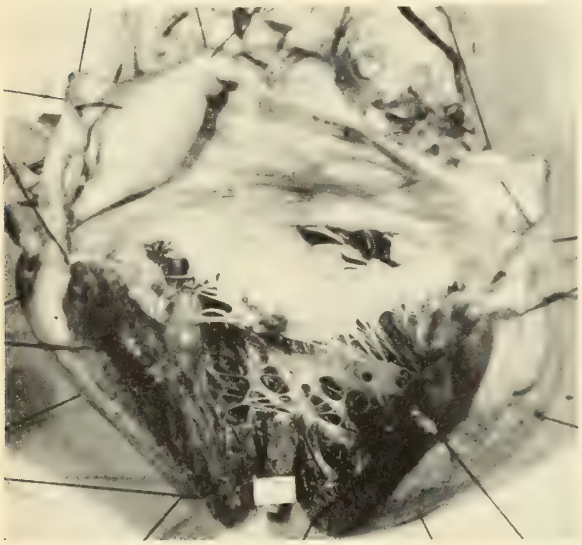

Fig. 3. Cor biloculare opened from the dorsal aspect, revealing common atrial and ventricular cavities, a bicuspid atrioventricular valve with an anomalus valve-like defect in the anterior leaflet and bacterial vegetations on the same leaflet.

erythrocytes per cubic millimeter. The hematocrit was 76 per cent. The coagulation time was 9 minutes and the bleeding time was 3 minutes. The total plasma protein was 7.7 grams per cent. The venous pressure was 9 cm. of sodium citrate. The arm to tongue circulation time was 21 seconds and that of the arm to lung was 8.5 seconds. Repeated attempts to perform blood volume determination were made, but were unsuccessful because of the high hematocrit and the resulting hemolysis of the blood.

Dr. Leo Rigler found complete situs inversus and some enlargement of the heart, apparently chiefly in the right ventricle. The pulmonary arteries were clearly visualized and the one on the right side was in normal position but rounded out in an unusual fashion. There appeared to be a dilated superior vena cava. Vascularization of the lungs was good. Dr. Helen Tausig of Baltimore suspected that there might be a single ventricle and advised deferment of operation until further knowledge of operative procedures on this type of lesion was obtained.

Five weeks after returning home, he failed to awaken in the morning. The heart tones were barely audible, and the pulse was not palpable. The heart rhythm was grossly irregular. The rate progressively slowed, and the patient expired without regaining consciousness.

Autopsy

The necropsy revealed the following significant abnormalities: situs inversus subtotalis, cor biloculare, transposition of the aorta and pulmonary artery, pulmonary stenosis, absence of ductus arteriosus, a streptococcic endocarditis on the atrioventricular valve leaflet, dilatation of cardiac cavities, chronic passive congestion of lungs, liver and spleen, and other lesser anomalies to be described.

The apex of the heart pointed to the right and its right border was 7 cm. to the right of the midsternal line while the left border was 4 cm. to the left. The pericardial sac had smooth, shiny, noninjected surfaces free from adhesions and contained only a few cubic centimeters of watery fluid. The heart weighed 410 grams. There were two cavities (Fig. 3). No trace of an interauricular or interventricular septum could be made out, except that there was a rudimentary, pouchlike space on the left lateral wall of the enlarged ventricular cavity. This rudimentary ventricle would barely admit the tip of the index finger and measured about 3 by 2.5 by 1.5 cm. The atrioventricular valves were two in number, each of approximately equal size. The anterior leaflet seen in Figure 3 had a rudimentary leaflet near its base with fairly normal appearing chordae tendinae distributed about its margins, so that this valve within a valve appeared to be competent. It measured 4 cm. in its greatest dimension. The chordae tendinae passed down into the rudimentary pouchlike ventricle described above and attached themselves to its inner surface. There were small granular, somewhat friable, pinkish gray vegetations at two sites on the atrioventricular leaflets as seen in Figure 3.

The aorta had its origin in almost the exact site of the usual origin of the pulmonary artery, i.e., anterior and slightly to the right, while the pulmonary artery had its origin posterior and slightly to the left. The aortic valve leaflets were not unusual. The aortic wall was distinctly thinner than average and had no atherosclerosis. The pulmonary artery leaflets were fused in such a fashion as to leave a slitlike opening which could be rounded out to about 0.8 centimeters in diameter. The margins of the slitlike opening were roughened, irregular, and had bits of calcium deposits which could be easily visualized on an x-ray plate of the removed heart. The first inch of the pulmonary artery averaged about half normal size, with a gradual increase in its diameter. This gradual dilatation extended up into the right pulmonary artery which became somewhat larger than normal. The left pulmonary artery branched off rather sharply and almost at right angles as a vessel about one-third of its normal size. The walls of all pulmonary arteries were extremely thin, measuring less than 1 mm. in thickness, and had the consistency of gutta percha. There were four principal branches off the arch of the aorta instead of three, there being a right subclavian and right common carotid instead of the usual right innominate artery. There was a ringlike marking with slight constriction of the lumen at a point just beyond the left subclavian artery at the site of the usual coarctation. No ductus arteriosus whatever could be found, not even a rudimentary band. The superior vena cava and inferior vena cava opened into the common atrial cavity on its left side, while the four small pulmonary veins, each averaging about 1 centimeter in diameter, opened separately to the right of the midline into the atrial cavity.

Evidence of confusion of development of the somatic and visceral elements, in this patient with almost complete situs inversus, were noted, in that the second portion of the duodenum was in its usual site to the right of the vertebral column and the common duct passed down to it in the usual manner. The aorta passed down the left side of the vertebral column, and the esophagus was to the right. Also, the attachment of the mesentery of the small intestine to the retroperitoneum was in its usual diagonal down to the right lower quadrant. The pancreas formed an irregularly rounded mass without a body or tail, measuring about 6 cm. in diameter. The spleen weighed 560 grams and was almost completely divided into two fairly normal shaped spleens. The microscopic examination revealed a most remarkable dilatation and congestion of endothelial-lined sinusoids, thin-walled arteries and veins throughout the myocardium. There was moderate evidence of chronic passive congestion in the lungs, liver, spleen and kidneys. The body had been embalmed so that

A HISTORY OF MEDICINE IN SCOTT AND CARVER COUNTIES

Biographical Dictionary

(Continued from May issue.)

Carl Augustus Entrup was born June 16, 1857, in Shakopee. He received his literary education at the public school and at the Minnesota Valley Academy, and read medicine in connection with his other studies, under Dr. M. H. Manson. After the death of his father, he taught school one year and in 1877 went to the University of Michigan, where he spent three years as a medical student. After receiving his diploma, in 1880, he returned to Shakopee and there practiced medicine until the time of his death in 1893. He was a very skillful general surgeon who later chose to specialize in eye and ear diseases. In 1891, when a boy at Jordan suffered lacerations of the face in an explosion, Dr. Entrup was called upon by the physician in attendance, because he was the only man in Scott County or adjoining counties capable of performing the surgical operation required. He was a member of the Scott County Medical Society, and of the Minnesota State Medical Society.

Dr. Entrup died in Shakopee in 1893 of pneumonia.

J. C. Erickson came to Jordan in 1861. He was a medical graduate and practiced medicine in addition to running a large drugstore. He remained for thirteen years and probably longer.

C. J. Fisher located at New Prague in 1894.

H. P. Fischer, a graduate of the Detroit College of Medicine, settled in Shakopee in April, 1894. His card read:

Dr. H. P. Fischer, M.D.
Physician & Surgeon
Office over Duetch & Zettel's Drug Store
Speaks German fluently

He soon became known as a good surgeon, and in a manner he filled the place that Dr. Entrup's death had left empty. In June, 1895, he married Philomena Huck of Berlin, Ontario, his former home. His popularity brought him many patients in Shakopee and the small towns in that part of the county. During the period 1897-1900 he served as county physician, and in 1897 and 1899 held the position of city health officer for Shakopee. In November, 1899, he recommended to the board of county commissioners that an operating room be fitted out at the county poor house, as there was no such provision in the county and it was needed sadly. On motion, he was authorized to purchase the necessary furnishings.

Doctor Fischer died January 24, 1940, as a result of an automobile accident in Minneapolis.

Charles F. Forssman was born in Sweden, July 4, 1836, and in that country studied medicine and received his diploma. He came to America and to Carver County in 1869 and practiced until his death in Hancock Township in May, 1887.

J. H. Frank, an eclectic practitioner, was graduated from the Minnesota College Hospital in 1882 and from the American Medical College, St. Louis, in 1883. He followed his profession in Chaska from about 1886 to 1896. In February, 1891, he married Mrs. Lillian Marsland of Argyle. About 1897 he moved to Anoka, where he remained a number of years.

D. S. French was a physician of Shakopee in the 1860's. He died there in May, 1867, at the age of fifty-five years.

Louis Gothelf was an early practitioner in Waconia, where he settled about 1864. He practiced medicine until about 1868, when he opened a general store. His business failed in 1872; he may have left the county at that time. He was an active Democrat, and in 1867 he served on the board of county commissioners.

S. D. Grant located in Watertown, Carver County, about 1869. He purchased a drugstore there in 1872; his advertising card read as follows:

Dr. S. D. Grant
Physician & Surgeon
And Dealer in
Drugs and Medicines
Paints, Oils, Glass, Putty
Books & Stationery
Everything belonging to a first class stock
Physicians'
Prescriptions carefully compounded
Also a choice stock of
Family Groceries and
Provisions
Watertown Minnesota

During the years 1873 and 1874 he acted as deputy county physician. In October, 1874, he was killed by a boiler explosion at Watertown.

William A. Griffin was one of the pioneer doctors of the Minnesota Valley and the first resident physician in the county of Carver. He was born in New Hampshire and was a graduate of Dartmouth College. Probably he was not trained in any medical school, as he practiced under the Exemption Law of 1883. In 1857 he located at Carver, and remained there until his death in 1899. During these years he held many public offices. He became the first justice of the peace of Carver and was the village president and treasurer. He was postmaster for the year 1865-1866 and assessor in 1870. During the Civil War he served as examining physician to the Carver County Volunteers. He was elected county physician in 1872, and late in life he was appointed health officer of Carver. He owned a drugstore at Carver and for many years was a prominent businessman in the village. His death came from heart failure at the age of seventy-five years. He was at that time the oldest practicing physician in the Minnesota valley east of St. Peter.

Charles T. Grivelly, the son of Dr. James Grivelly (of Young America, Carver County, and later of New Market, Scott County), was a non-graduate, licensed in Minnesota in 1896. In 1892 he went to Switzerland to study medicine. On his return to Carver County he settled in Waconia, but in 1899 he returned to Young America, as the field had been vacated by his father. He was a popular young physician.

James Grivelli (known later as Grivelly) was graduated from the medical department of Iowa State University in 1887; and, having been licensed to practice in Minnesota in April of the same year (certificate No. 1375), he came from Arlington and settled in Young America, Carver County, in June. In the fall of 1888 he departed on a journey to Switzerland, his fatherland. The following March he returned to Young America, where he practiced until 1899. His large practice extended to Mayer, Norwood, Bongaard, Schnappsburg, Waconia, Heyd's Lake and Brownlin. Since he spoke German, he was popular among the German residents, as well as among the English speaking settlers. In 1893 he was elected to the pension examining board at Glencoe.

Dr. Haas was an early physician at Chaska about 1874.

John Habenicht, a graduate of the University of Prague, Bohemia, in 1864, came to Scott County, or thereabouts, soon afterward. After practicing two years in Jordan, in 1876 and 1877, he moved in 1878 to New Prague. After three years he returned to Jordan, where he was welcomed back by the German people of that town. His stay terminated after nine months, however, when he went into partnership with Dr. Landenberger of New Prague. Evidently patients were scarce, for in March, 1882, he left; and for four years he "played in various theaters in some of the large cities."

In February, 1886, Dr. Habenicht returned to practice in New Prague, and there with Dr. Landenberger opened a hospital for the treatment of chronic diseases. Their card read:

> Dr. J. Habanich [*sic*] Dr. J. Landenberger
> Habanich & Landenberger
> Physicians & Surgeons
> Are now ready to treat all kinds of Chronic diseases, male or female. The treatment will be at the New Prague Hospital, owned by the Doctors. All communications will be answered free of charge.

But even this project was not successful, and the doctor started out again to find a more fertile field. He moved to Glencoe in October, 1887, then to Waconia, then returned again to New Prague in December of the same year. He was licensed in Minnesota under the medical practice act of that year, and he held Certificate No. 1475 (R). In 1894 he was in Owatonna.

Harry A. Halgren practiced for many years in Watertown, beginning in the late nineties, and was well known in Hollywood and St. Bonifacius also. A non-graduate, he was licensed in Minnesota in 1896. In 1900 he was elected coroner of Carver County.

John B. Hall, a homeopathic physician, opened an office for practice in Shakopee in May, 1867. Previously he had been the proprietor of Hall's Homeopathic Pharmacy at Cleveland, Ohio. Not long after his arrival he suffered the loss of much property, including his office fittings, household furniture and library, in a fire.

Everett C. Hartley was a homeopathic physician who settled in Carver in January, 1886. He had been graduated from the Chicago Medical College in 1879, and he held Minnesota License No. 387 (R), issued on November 24, 1883. In the year following his arrival in Carver, he married Bertha Strache of that town. He was a very promising young physician and his practice grew rapidly. He drove a spanking team of horses, and was called to nearly every accident in that part of the county, including Chanhassen, East Union and Jordan, Scott County. He was often mentioned as a first-class man professionally, and he held many civic offices. In the years 1889 through 1891 he served on the Carver board of health, and in the period 1896 to 1900 was "the best coroner this county ever had." In 1897 he became a member of the pension examining board at Shakopee and continued in that office for several years. He prospered financially to the extent of building a new home, keeping a fine stable, taking frequent trips to the Twin Cities and to the Fair at Chicago, and going on annual hunting trips in Dakota. In December, 1898, he took a month off to do postgraduate work in Chicago, leaving his friend Dr. C. W. Malchow of Shakopee to attend his patients in both Chaska and Carver. After his return, Dr. Hartley practiced in Carver until his death in 1928.

Dr. Hoeffken practiced at Schnappsburg in 1893.

George B. Holmes practiced in Carver in 1870.

S. M. Janes, a homeopathic physician and a graduate of the Hahnemann Medical College of San Francisco in 1888, was licensed in Minnesota in 1892. He settled in Jordan about 1893. He was intensely interested in both politics and medicine. In 1895 he spent a fortnight visiting Twin City hospitals and a month in New York City looking up the latest in medicine and surgery. To quote from the *Scott County Argus,* an issue of 1895: "The doctor is not one of those whose contentment has robbed him of his ambition and his recent expensive trip shows that he is bound to have the best in his profession and keep abreast of the times." In 1898 he was appointed one of the county physicians and served in that capacity for several years. About 1900 he established a private hospital in Jordan.

David A. Kirk was graduated from the Detroit Medical College in 1888 and was licensed in Minnesota in 1889. He practiced in Jordan, Scott County, about 1890 or 1891. Later he was in Le Sueur (see the medical history of Le Sueur County).

John Knotz, a graduate of Hamline University in 1897, came to Cologne from Minneapolis in April, 1898. He spoke both English and German and was an old practitioner. Cologne had never had a physician previous to that time, and the village was anxious to keep him. His practice extended to Benton and Anoka, and he was well patronized. He could not make up his mind

to stay, and moved to Story City, Iowa, for a few months but returned again to Cologne where he remained for several years.

J. C. Koch located in Norwood about 1894, having previously practiced in Waconia. After residing for five years in Norwood, he died at a Minneapolis hospital from complications following the removal of his appendix.

C. H. Kohler, son of S. B. Kohler of Watertown, Carver County, and brother of Dr. F. G. Kohler of Forest Lake, practiced in Shakopee about 1890, then moved to Glencoe and later to Minneapolis.

David La Framboise was an Indian doctor, one of the local Sioux, who lived at Shakopee during the nineties and was also well known at Hastings.

John Landenberger, Jr., established himself in New Prague about 1871. He was well supported by the local Democrats in politics, and for several years he served as coroner of Le Sueur County. New Prague is situated on the county line, and consequently Dr. Landenberger's practice extended into both counties. In 1886 he associated himself with Dr. John Habenicht and the two physicians opened a hospital for the treatment of chronic diseases; as noted earlier, the project was of short duration. Dr. Landenberger, who practiced under the Exemption Law of 1883, remained in New Prague for many years.

John Landenberger, Sr., settled in Helena, Scott County, in 1854 and lived there until 1875, when he moved to Portland, Oregon. He practiced in Portland for two years and was buried there when he died in 1877 at the age of fifty-nine.

Benedict Lehmann came to Watertown, Carver County, in 1856. In the fall of that year he laid out the village of Helvetia on the Crow River. How long he remained in Carver County is not known.

Dr. Lening, a graduate of a German University, settled in Blakely Township, Scott County. He died there in 1858.

E. H. Lewis came from Washington, D. C., and settled in Carver in August, 1870. Many physicians had come for a brief stay at Carver, then passed on in search of a better field. Dr. Lewis came better recommended than most (he had had eight years of experience), and Carver was then in need of a physician who could handle the sudden onslaught of epidemics that came in that year. Soon after his arrival Dr. Lewis was busy day and night. He was, without doubt, the most popular man in town, and his social position as well as his professional standing was soon assured. His practice extended throughout the county and into Scott, Sibley, and McLeod Counties. On several occasions he was elected to public offices: in 1870, as deputy county physician and in 1871 as examining surgeon for Carver County. In the latter year he served also as Commander of Baxter Post No. 25 of the Grand Army of the Republic, and as president of the newly organized Carver Literary Society. In 1872 he opened an office in Chaska and commuted every day. In the following spring he took his younger brother, Dr. Frank E. Lewis, into partnership in the Chaska office, where the latter remained for a short time.

Dr. E. H. Lewis died at Carver in July, 1884. At the time of his death, he was a leading member of the profession in the Minnesota Valley.

Frank E. Lewis, as noted above, was a brother of Dr. E. H. Lewis of Carver. He was a graduate of Rush Medical College, and practiced in Carver and Waconia during the first half of the year 1872. The following spring, he practiced at Chaska in partnership with his brother. In June, 1873, he moved to Alexandria, Douglas County, where he formed a partnership with Dr. Godfrey Vivian of that town.

Charles Lord was born in Westmorland, New Hampshire, on July 22, 1817. At the age of seventeen years he went to Augusta, Georgia, where he spent three years in the study of medicine. He married in 1839, and five years later entered the office of Dr. Woodhouse in New Hampshire, with whom he stayed three years as a student. In 1847 Dr. Lord began the practice of medicine in his native town, and continued there until 1849, when through the influence of relatives of his wife he moved to Pittsburgh and there entered into practice with Dr. Oldshoe. When his health failed him, he sought the climate of Minnesota and arrived in Carver County in the spring of 1854. He settled in the township of Chanhassen. In the fall of the same year he moved to a farm in Eagle Creek Township, two miles east of Shakopee. His claim covered 160 acres, half of which he sold, and the remaining part of which he farmed until 1864. Then, having regained his health, he settled in Shakopee and actively engaged in the practice of his profession.

Dr. Lord had a large clientele throughout Scott County. For a time, about 1867, he had his office at Jordan, but in a few months returned to Shakopee. He held many public offices, and was one of the first county commissioners. For years he was an active member of the town board of Eagle Creek and also a member of the school board for that district. After moving to Shakopee, Dr. Lord became a member of the board of management of School District No. 2, which position he held at the time of his death. He was chosen to represent the Third Ward of the city as alderman at the first election under the Shakopee city organization (1870). He held that position for six years, at the end of which he declined re-election because the work entailed frequent absence in the discharge of professional duties. He was a prominent member of the Masonic Lodge, and was active in the Episcopal Church. He continued to practice medicine until his death, from Bright's disease, in May, 1881.

Dr. Lord was spoken of, by a contemporary, as a "conscientious and painstaking physician."

John A. Macdonald, born in Scotland in 1809, came to the Minnesota River valley, settling in the vicinity of Chaska about 1859, and was at that time known as a physician. He is recorded in the *Official Register of Physicians in Minnesota, 1883-90* as having graduated in 1867 from the College of Physicians and Surgeons at Keokuk, Iowa. In 1864 there was a severe epidemic of smallpox in the county, and Dr. Macdonald did a great deal to alleviate distress among those afflicted. In April he wrote an article for the *Chaska Valley Herald* in which he called the people's attention to sanitary and preventive measures. In October, 1865, he left Chaska to serve as First Assistant Surgeon of the Second Min-

nesota Cavalry. Upon being relieved from duty, he returned to practice in Chaska; his card published in January, 1866, read as follows:

> Dr. John A. Macdonald
> Physician and Surgeon
> Late 1st Asst. Surg. 2nd Minn. Volts. Cav'y.
> Respectfully intimates to the inhabitants of Carver County that he has again opened an office in Chaska. Where he will attend as before to every kind of business connected with his profession. Surgical operations scientifically performed. Chronic diseases successfully treated and all other calls promptly attended to.

In October, 1866, he moved to Saint Paul, leaving Chaska and the nearby country much in need of a physician, as he had been the only one there. It is possible that he then took a course in medicine at Keokuk, Iowa. Later he returned to Chaska, but left to serve in the army again, as contract surgeon, in 1884. In March, 1886, he located at San Diego, California, but again returned to Chaska. Two years later he moved to Chicago, giving up his practice on account of poor health, but again he returned, and remained in Chaska up to a month prior to his death, which occurred at a Minneapolis hospital on November 30, 1890. He was the father of the Honorable John L. Macdonald, who lived in Shakopee for several years.

William F. McCarthy, a graduate of the Saint Paul Medical College in 1880 and the University of Minnesota in 1889, came to New Prague from Minneapolis in the year 1890. After two or more years of practice there, he moved to Jordan, where he remained for many years. During the years 1894 through 1896 he served as county physician. He was active in relieving those afflicted during the severe epidemic of diphtheria in the period of 1896-1898, serving part of that time in his capacity as county physician. He served as health officer of Sand Creek during the year 1897 in the worst part of the epidemic. He also held the position of pension examining surgeon in 1894.

C. W. Malchow settled in Shakopee as a successor to Dr. A. A. Sabin after the latter's death. He came from Lester Prairie, Minnesota. At the time of his arrival (March, 1896) he was less than thirty years of age and unmarried. Almost immediately he became a part of the social life of the town. He made frequent visits to Minneapolis, as his parents and sisters lived there. Also he was an active member of the Alumni Association of the Medical Department of Hamline University, and served as president of the association for several years. In June, 1897, he gave up his practice in Shakopee for a year of clinical work in the hospitals at London, Paris, Berlin, Munich, Vienna, and New York. He went first to Guy's Hospital in London, then studied for a time under Koch, in Berlin. He returned to Shakopee in March, 1898, and was considered the leading physician there at the time. In that year and the next he held several civic offices, among them that of city health officer. Apropos of his professional ability, it is of interest to note that he received, in 1894, a gold medal awarded for the highest examination during 1893-1894 by the Minneapolis College of Physicians and Surgeons.

In May, 1900, Dr. Malchow sold his medical practice, office equipment, horses and vehicles and went to Europe again for a year's recreation and

study, intending to perfect his knowledge in a special line, that of diseases of the digestive organs. When he returned in December of that year, he established himself in Minneapolis and became professor of anatomy at the Minneapolis College of Physicians and Surgeons. A more dramatic chapter of his life came after 1900, when he wrote and published a book, *The Sexual Life,* too progressive for the first decade of the twentieth century, and was sentenced to the penitentiary.

J. Manning, a graduate of the Iowa College of Physicians and Surgeons, established himself in Cedar Lake, Scott County, in March, 1877, as a schoolteacher. In the fall of 1877 there was a controversy between him and the county superintendent, and Manning was deprived of his certificate. In 1878 he practiced medicine at Hamilton, and in September of that year he ran for the office of superintendent of schools in Scott County, but lost. During 1879 and 1880 he continued the practice of medicine at Cedar Lake.

M. H. Manson came to Shakopee, Scott County, in October, 1875, succeeding Dr. L. S. Thompson. He was a native of Maine and made frequent visits there. In 1880 he held the position of United States pension surgeon for Scott County. Both Dr. and Mrs. Manson were well liked and active in the social circles of Shakopee. Dr. Manson became a member of the Shakopee post of the Grand Army of the Republic when it was organized in 1886, and he served as post surgeon that year. In 1887 he moved to Minneapolis.

N. H. Marshall, a graduate in medicine from the University of Minnesota in 1892, settled in Chaska, Scott County, about 1895. He was a prominent member of the profession and held several offices during the first years of his residence. In September, 1897, he received an appointment as pension examining surgeon at Shakopee and served as president of the board that year. In 1898 he served on the board of trustees of the Chaska Red Cross Aid Society, and in 1899 as physician of the Modern Woodmen of America, a fraternal organization then composed of many of the leading citizens. In October, 1898, when he expressed his intention of leaving Chaska for Park Rapids, he was induced to remain by the earnest requests of his many patients in the city and vicinity. In December of that year he was elected chairman of the board of health of Chaska. He remained in practice there until his death in 1930.

M. M. Mead came to Chaska to practice in September, 1871. He had formerly resided at Winona. After some years of practice he died in the Soldiers' home at Minnehaha.

Dr. Meek arrived in Young America, Carver County, about 1886. He gained an extensive practice in the town and nearby country. In 1887 he was made surgeon of the Major J. C. Becht Post, Grand Army of the Republic. In that year he moved to Glencoe.

R. S. Miles settled in Young America, Carver County, in December, 1872. He was a member of the Physio-Medical School. He met with a fair degree of success in the county and stayed there several years.

(To be continued in the July issue.)

President's Letter

NATIONAL HEALTH ASSEMBLY, 1948

The National Health Assembly held in Washington last month marked the second time in ten years that such a conference has been called. In retrospect, both conferences appear quite different. A dangerous undercurrent—the constant push for nationalized medicine—was present in both; but this second conference leaves the cry for compulsory health insurance somewhat muted. In its fight to preserve private practice, medicine has apparently dealt some telling blows, but it should be obvious to every thinking medical man that the constantly expanding efforts of the profession to provide more adequate and more equitable medical service to the general public will have to be promoted relentlessly and ever more unselfishly if the arguments of pro-nationalists are to be routed.

The first edition of the health assembly in 1938 was definitely a packed conference with physicians considerably outnumbered by social planners and others committed to support of federally administered health programs. Pressure from the American Medical Association on Federal Security Administrator Ewing, who called the 1948 assembly, resulted in a much fairer proportion of physicians among the groups represented. Out of 800 delegates to the recent conference, about 200 were doctors. Also represented were state health departments, social workers, labor, agriculture and various other organized groups.

National meetings of this kind lend themselves well to behind-the-scenes activities of federal bureaucrats. Organized medicine must, therefore, keep in closest touch with these developments. The Minnesota State Medical Association, just as many other state associations, sent representatives both to observe and to participate in this conference.

Called at the request of President Truman for the purpose of developing "feasible health goals for the next ten years," the National Health Assembly examined several national health problems. There were fourteen sections, each discussing a particular question. Worthy of note is the work of the section which discussed the nation's need for medical care. It was in this section that the largest number of delegates registered. It is interesting that in spite of so many diverse opinions held by those in this section, many areas of disagreement were apparently cleared.

The findings of each of the sections will be published in full at a later date from Mr. Ewing's office, but from the preliminary reports it is apparent that all sections took their work very seriously, and all approached their problems from the community level rather than from the national level. Of course, the fact that the full report of what took place at the Health Assembly is to be made by Mr. Ewing leaves the field wide open for him to present whatever viewpoint he desires. Delegates apparently, however, did recognize the fact that health problems cannot be solved by physicians and health authorities alone; only in a couple of instances was emphasis given to the need for federal assistance. Surprisingly, even in the medical care section voluntary health insurance took precedence over compulsory plans; and all groups represented in this section endorsed extension of voluntary prepayment programs.

Quincy Howe of the Columbia Network broadcast a summary of the conference in which he praised doctors who had attended for taking time to work with the National Health Assembly. He said that the fact they had shown themselves so co-operative, so understanding and so open-minded, seemed to him the most promising and important development of the whole meeting.

We of the medical profession must bear in mind that the people at this conference are the people with whom we must work in accomplishing health objectives. We have pledged ourselves to co-operate with responsible groups toward the realization of improved health for Americans and to support any *feasible* programs toward that end. We reaffirm that pledge now. Ours is the responsibility of offering constructive leadership in the health field where our experience and training have qualified us to speak.

President, Minnesota State Medical Association

B.A.L. IN HEAVY METAL POISONING

ONE of the important discoveries from the medical standpoint made during World War II was that of B.A.L. (British Anti Lewisite) by English scientists. In 1909 Erhlich first stated that the toxic action of arsenic was due to its combination with sulfhydrl groups (SH) of the tissues. Many other investigators have ascribed that metallic compounds combine with these thial groups of the tissue and thus inactivate these constituents necessary for life and function. English scientists—Peters, Stocken and Thompson—working on this theory proposed by others discovered 2-3 dimercaptopropanol (B.A.L.) as an antidote for lewisite poisoning. They used B.A.L. in an inunction and showed that it protected the skin against arsenical vesicants, stopped systemic effects and increased urinary output of arsenic.

These scientists showed that B.A.L. (CH_2-SH-HC-SH-H_2-COH) produced its effect by using its sulfhydrl groups (SH) to compete with the tissue sulfhydrl groups for the poison. It not only prevented the toxic reaction but could reverse the reaction, the latter being of extreme importance in cases of poisoning. They further revealed that B.A.L. was a dithial containing two (SH) groups and as such had greater stability and greater affinity than monothial groups.

There are three of these mercaptans: (1) B.A.L., (2) B.A.L. glucoside and (3) thiosorbital. B.A.L. glucoside is not sufficiently available in its pure form. Thiosorbital has an advantage in that it is water soluble and can be given intravenously. B.A.L. itself is commonly used and is most effective in treatment.

B.A.L. is of great value in the treatment of bichloride of mercury poisoning. Longcope reports twenty-three patients taking doses ranging from .5 to 20 gms. of this substance with only one death. He reported the mortality rate at Johns Hopkins prior to advent of this drug as being 12.9 per cent and at present only 4.4 per cent. Eagle reports excellent results using B.A.L. in treating the complications of arsenic therapy. These complications included toxic encephalitis, agranulocytosis, aplastic anemia, jaundice, massive overdosing with oxophenarsine and arsenical fever. The most conclusive evidence of its efficiency was in toxic encephalitis and agranulocytosis. There is one very encouraging report of a case of optic neuritis due to tryparsamide successfully treated with B.A.L. and one case of lead poisoning has been reported in which treatment was successful. Three cases of tellurium poisoning were recently treated with complete recovery. Experimentally, B.A.L. is useful in treating poisoning in animals produced by antimony, bismuth, chromium and nickel, but has been reported as not being useful in the treatment of poisoning in animals by lead, thallium and selenium. Because of its ability to reduce methemaglobin to hemoglobin it should prove useful in treatment of poisoning due to anilin compounds such as acetanilid and phenacetin.

The recommended dosage of B.A.L. is from 2.5 mg. to 5 mg. per kilo of bodyweight given at four hour intervals. B.A.L. is prepared as a 10 per cent solution in peanut oil for intramuscular use. In bichloride of mercury poisoning 5 mg. per kilo is recommended for the initial dose followed by 2.5 mg. per kilo at two to four hour intervals for the next twelve hours; thereafter 2.5 mg. per kilo may be given b.i.d. until recovery occurs. The reactions from B.A.L. therapy included nausea, vomiting, headache, burning sensation in eyes and feeling of constriction in the chest. No serious reactions from B.A.L. have been reported. Adrenalin may be used in the treatment of any of the reactions.

Thomas J. Kenyon, M.D.

INDUSTRY AND THE OLDER AGE GROUP

WHATEVER the reasons may be, a man or woman who has reached the age of forty-five may well have the feeling that he or she is discriminated against when it comes to obtaining a job. Our laws relating to responsibilities of employers towards employes doubtless constitute one

reason for this discrimination. Probably more important is the feeling on the part of the employer, which is more a tradition rather than founded on fact, that youthful employes are more desirable than those in the group over forty-five.

A series of articles on the problems presented by our aging population, written by Dr. Howard A. Rusk, have been appearing in the *New York Times* and are most constructive in nature. He calls attention to the fact that although certain jobs requiring agility and strength are admittedly better filled by the youthful, there are certain positions requiring judgment, experience, and skill which are better filled by the older group. Experience and age, up to a certain point, are an advantage to judges, teachers, artists, architects, doctors, and others. With an ever-increasing larger percentage of the population constituting the older age group, the importance of society's furnishing adequate employment for this group becomes apparent. Dr. Rusk mentions some of the steps which have been taken to meet this situation. In New York, the Federation Employment Service, an affiliate of the Federation of Jewish Philanthropies, has recently made a campaign to secure employment for those over forty-five and to educate the public to the idea of the fitness of older people for employment. The response of employers all over the country is said to have been remarkable, and they have agreed to place orders for older workers. With the slogan "Experience, Loyalty and Skill Come with Age," attention is drawn to the fact that older workers make good employes. With family responsibilities, they are more stable in their jobs and actually, according to U. S. Bureau of Labor statistics, have fewer accidents.

Dr. Rusk mentions the Forty Plus Club in New York City, composed of men over the age of forty who have had extensive executive experience, which has been successful in obtaining jobs for over 70 per cent of its 3,000 members.

These organizations are constructive in nature in meeting the evident need, not only of putting to work more of those chronologically in the older age group, but still physiologically young and able to be productive for the good of themselves as well as their communities. The tragedy of old age is when one's mental and physical disabilities force him to become entirely dependent on society. Many in the older age group need not be dependent on others. This is a fact which needs emphasis.

RADIO "BUNK"

WHEN a physician hears over the radio, as he so frequently does, that the majority of his profession recommend a certain brand of cigarette, or that dentists prefer a certain dental powder to a cream, or that nurses who have to be dainty use a certain kind of soap, he is inclined to react with the word "bunk," whether expressed or not.

While many physicians smoke, they doubtless use as great a variety of brands of cigarettes as the general population. While sampling of the profession in regard to cigarette preference may have been carried out, we challenge the correctness of the conclusion that a majority prefer any one brand. The same applies to any majority preference on the part of the dental or nursing profession. We are not informed on the brand of cosmetics used by Hollywood stars, but we have the feeling that most of them use too much of everything which does not improve on nature. We have heard that most of them have capped incisors and deem this necessary as screen magnification tends to show up dental imperfections.

How long is the opinion of the profession going to be falsely broadcast on the air? Such falsification which must be obvious to the radio audience only detracts from the confidence which the radio industry must desire for its broadcasting.

SOCIALISM VERSUS COMMUNISM?

"There could hardly be a more perverse and mistaken idea than the idea that you can fight communism with socialism. So-called 'gradual' socialism is at best a halfway step toward communism. The economic ideals of socialism and communism are identical. Both believe in government ownership and operation of the means of production. Once this ownership and operation become sufficiently extensive, the government has economic life-and-death powers over the individual. It can say where he must take his job, what job he must take, or whether he can take a job at all. And once the government has this power, the liberty of the individual has in fact, if not in form, disappeared. As Alexander Hamilton pointed out in the Federalist Papers a century and a half ago, 'A power over a man's subsistence amounts to a power over his will.'"—HENRY HAZLITT.

A NEW CANCER EDUCATIONAL SERVICE

A. H. WELLS, M.D., Chairman
Cancer Committee, MSMA

A new and valuable service in the fight against cancer will soon be available to the physicians of the state.

The House of Delegates and Council of the State Medical Association has approved a new cancer educational service, which will offer help without expense to local physicians, hospital staffs, or county medical societies.

Three functions provided by the service will aid doctors in controlling cancer, which takes an annual toll of 180,000 lives in the United States. Recognized as a major health problem, cancer has become second only to heart disease as a cause of death, and ranks first for women between the ages of thirty-five and fifty-four. Fortunately, an enlightened public is now seeking earlier treatment, the physicians are well prepared with knowledge and facilities, and science, through research, continues to offer hope of an ideal preventive or cure.

Educational Services

The Purpose.—To establish a cancer educational service which would be readily available to the Minnesota county medical societies, hospital staffs, and individual physicians.

Collaborating Physicians.—Will be a group of recognized specialists who are qualified to give authoritative opinion on some phase of cancer diagnosis or treatment. The collaborating physicians will be men with the above qualifications selected by the Cancer Committee of the State Medical Association who will volunteer to take part in the educational service program. This group may be added to at any time to include physicians for special problems.

Plans.—The Cancer Educational Service will offer three types of service without expense to local physician, hospital staff, or county society.

(a) A team of from three to five members of the Cancer Educational Service will be offered to any component society of the Minnesota State Medical Association for a one-day cancer institute.

(b) One or possibly two members of the cancer educational service will be available to meet with any hospital staff in the state, no matter how small, for an afternoon or evening of cancer discussion.

(c) A free cancer correspondence service through which any physician may write confidentially to the Cancer Educational Service regarding any problem concerning a cancer case. Such inquiries will be referred to the member of the Cancer Educational Service who seems best qualified to answer this particular inquiry. The names of the physicians making the inquiry will not be divulged. The opinion obtained by the Cancer Educational Service will be forwarded on to the physician making the inquiry. Inquiries which seem to be of special interest and the opinion obtained will be published in Minnesota Medicine from time to time, without the names of the physicians being used.

Headquarters.—The headquarters of the Minnesota State Medical Association shall be the office of the Cancer Educational Service of the Cancer Committee.

Operation.—The Cancer Educational Service will be carried on under the direction of the Cancer Committee of the State Medical Association. All communications relative to this service shall be mailed out on special stationery of the Minnesota State Medical Association Cancer Committee carrying the address of the State Medical Association Headquarters in Saint Paul. The Cancer Control Division of the Minnesota Department of Health will finance a secretarial service to aid in the operation of the educational service. This secretarial service will take care of scheduling the collaborating physicians for county medical society and hospital staff meetings. Also this service will submit correspondence inquiries to the selected collaborating physician and transmit the reply to the inquiring physician. The Cancer Control Division of the Minnesota Department of Health will aid the Cancer Committee in every way in promoting and carrying out these institutes and staff meeting conferences.

Financing.—This service will be principally financed through funds of the Cancer Control Division of the Minnesota Department of Health, but other organizations, such as the Minnesota Division of the American Cancer Society may also contribute to this service. Collaborating physicians will be paid an agreed stipend for the services rendered. This stipend tentatively has been set at $50 and expenses for each meeting in which the collaborating physician participates.

County Medical Societies.—The facilities of the Cancer Educational Service will be available in the territory of any component county medical society as soon as official approval by the county society or its authorized officers has been given for the cancer committee educational service in the territory.

POVERTY AND DISEASE

It is well known that the incidence and severity of illness are greater among the urban poor than among the more prosperous groups. Ignorance is a factor in promoting high sickness rates, but ignorance is in part a result of poverty.—*Medicine in the Changing Order, Rep. New York Acad. Med. Comm., The Commonwealth Fund, 1947.*

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

CONGRESS CONSIDERING DRAFT OF PHYSICIANS

Planning for the possibility of another national emergency is naturally of vital concern to members of the medical profession, in view of the general confusion which reigned during the last war with regard to the utilization of medical personnel and facilities. These plans have, however, taken an unexpected turn with the appearance in Congress of a bill (H.R. 6401) which asks among other things that the President be authorized to draft certain members of the medical profession under the age of forty-five.

The House is now considering this bill. According to latest reports, the army, the air force, the navy and the marine corps under this bill can call in doctors so as to maintain a ratio of five doctors to every 1,000 men on active duty.

Here, in order of priority, are the qualifications making a physician under forty-five years of age eligible for call:

(1) If he accepted government aid in securing education or was deferred for that purpose and had no active duty as a commissioned officer.

(2) If he participated in the specialized training programs and served for less than twenty-four months.

(3) If he is under thirty-five and served less than ninety days on active duty.

(4) If he is over thirty-five and served less than ninety days on active duty.

(5) If his total active service is less than twenty-four months.

(6) If he comes under some other classification to be prescribed by the President.

AMA Protests Physician Induction

The AMA Council on National Emergency Medical Service which has been studying ways and means of bringing order out of chaos among medical ranks in time of emergency has protested to officials in Washington that provisions for inducting physicians included in H.R. 6401 are "unnecessary and discriminatory and constitute a reflection on the patriotism" of the medical profession.

Physicians throughout the country, both those called upon to serve in the armed forces and those left to provide medical care for the civilian population, met every demand for medical personnel without compulsion by law. There is certainly no reason to believe that physicians will not again respond in the same manner if the need should arise. Yet there is strong evidence in the present proposal that the federal government officials are not willing to accept this record of physicians as proof of their good faith.

On April 5 and 6 the Council on National Emergency Medical Service of the AMA held a meeting in Chicago to discuss plans for national defense against atomic, biologic and psychologic warfare. The Minnesota State Medical Association was represented by the Chairman of our Committee on Military Affairs. The work being done by this AMA Council typifies the willingness of American physicians to take the lead in strengthening our national defenses.

Medical Inventory Predicted

It has been predicted that in planning for national civil defense a number of physicians will be needed to serve full time with the Department of Civil Defense, assisted by a panel of medical advisers. The possibility is also strong that the army will call upon the AMA Council for a survey of medical personnel; a check on needs of civil and military organizations; and the establishment of physical standards for military service. The AMA will in turn ask state and county medical societies to co-operate.

A reactivation of the machinery for defense and war is now well under way nationally.

Selective Service would like to have a physician appointed to each of its local boards. Physicians will serve as examiners as they did for World War II, according to present plans. From this it can be seen that physicians will be asked for the same type of service in the event of another war as formerly, with the exception that should present legislation be passed physicians will also be drafted.

It is the opinion of the American Medical Association and its Council on National Emergency Medical Service that this would not give proper recognition to civilian needs. As in the last war, civilian doctors will find themselves shorthanded; the very problem which the Council is seeking to avoid will be re-created. There is, in addition, every indication that even more physicians will be needed on the home front in a future war because of the danger of atomic attack and the increasing possibilities for civilian involvement.

Ask National Civilian Medical Board

The Council on Emergency Medical Service is asking that there be established immediately a national civilian medical board, paralleling the functions of the National Security Resources Board, which would have charge of policies and programs for medical, health and sanitary services for the civilian population, for industry, for agriculture and for the armed forces during an emergency or period of national mobilization. This board is absolutely essential to prevent avoidable depleting of the supply of doctors to take care of the people at home.

The medical profession will undoubtedly have a prominent role in activating whatever plans for national defense are finally evolved. In addition to these responsibilities, every physician should be on the alert regarding his probable military status. The Senate military committee is considering a proposal to examine and classify physicians both physically and professionally and to assign every doctor to military or civilian duties. The idea is to have those physicians in the military service remain in private practice until their services are needed elsewhere. It seems very likely that definite steps will be taken by Congress in the near future to enact definite defense measures along the lines outlined here. It is assured that the Association will be kept informed on these developments.

MEDICINE AWAITS RESULTS OF NATIONAL HEALTH ASSEMBLY

To all outward appearances the recent National Health Assembly in Washington was a fair and hard-working conference, with a profusion of congratulatory messages exchanged among the participants at the conclusion of the sessions.

The question being asked by the medical profession today is—"What happens now?" That question will be answered only when the official published report of the deliberations and conclusions of the fourteen section meetings which were held is finally handed out from the office of Mr. Oscar R. Ewing, Federal Security Administrator, who called the Assembly at the request of President Truman.

From the preliminary reports and conclusions already briefly publicized, a number of highly encouraging developments have been noted, although it is too early to predict what the end result will be. Apparently, a real attempt was made to meet issues squarely and to be mutually tolerant. And although the followers of compulsory health insurance weren't by any means "converted" they did on several occasions admit that the principle of the voluntary prepayment plan is highly desirable and that these plans should be encouraged and extended. Physicians will want to keep in touch with the developments following this meeting.

Another Assembly Planned

The Executive Committee of the Assembly is planning to have another meeting to decide on future plans along these lines. They will discuss the advisability of holding such Assemblies periodically, perhaps every five years.

This Executive Committee represents part of the steering machinery of the Assembly. Members were appointed a month in advance by Mr. Ewing. The medical profession was outnumbered on the original panel, but additional medical representatives as well as members of other professions were placed on the committee when the discriminatory nature of the initial plans for the Assembly was pointed out by the AMA in an editorial in the *Journal.*

MSMA Represented at Conference

The Minnesota State Medical Association, at the direction of the Council, sent three representatives to the meeting; the Chairman of the

Committee on Public Policy attended as an official delegate, while the Chairman of the Council and the Executive Secretary served in the role of observer only.

Each of the 800 delegates, of whom 200 were doctors, was enrolled in one of the fourteen sections which were assigned to the discussion of a particular problem. Section subjects were: (1) Health and Medical Personnel, (2) Hospital Facilities, Health Centers and Diagnostic Clinics, (3) Local Health Units, (4) Chronic Disease and the Aging Process, (5) Maternal and Child Health, (6) Rural Health, (7) Research in the Service of Health, (8) Medical Care, (9) State and Community Planning for Health, (10) Physical Medicine and Rehabilitation, (11) Dental Health, (12) Mental Health, (13) Nutrition, and (14) Environmental Sanitation.

Most difficult assignment of the whole conference was the one handed to the section discussing ways and means of providing medical care. It was ably carried out by Dr. Hugh R. Leavell, professor of public health practice at Harvard, who acted as chairman and succeeded in bringing into agreement on a number of points a group of persons with the most widely divergent viewpoints possible. Members of the committee under Dr. Leavell were Dr. Ernst P. Boas, Physicians' Forum; Nelson Cruikshank, director, social insurance activities, AFL; Horace Hansen, general counsel, National Federation of Health Co-operatives; Dr. Thomas A. McGoldrick and Dr. James R. McVay, AMA; Harry Read, CIO; Dr. C. Rufus Rorem, Philadelphia Hospital Council; and Dr. Louis Wright, Harlem Hospital.

After heated discussions agreement was reached on seven points discussed. However, an eighth point was taken up, but according to the summary statement released at the close of the sessions, it was left unsettled. It will come as no surprise to physicians that Point Number 8 was the issue of compulsory national health insurance.

MENTAL HOSPITAL FIGURES RELEASED

An interesting report to come from the Mental Hygiene Division of the United States Public Health Service is one just released giving the national picture on conditions in mental hospitals. The report shows Minnesota standing about in the middle—neither much better nor much worse that the national average for such things as expenditures per patient; percentage of overcrowding, et cetera.

Figures summarizing the national picture from 1937 to 1946 reveal a gradual increase in the number of patients confined in mental hospitals; and although there has been some expansion, increases in facilities and personnel have lagged behind the increases in the number of patients. Percentages of overcrowding have increased several points; and whereas there were 5.8 patients for each employe in 1937, employes now are responsible for at least one more patient apiece.

Overcrowding in Minnesota institutions is about half as bad as the national figure—nationally there are 16.3 per cent more patients than facilities warrant, whereas in Minnesota there are 8 per cent more. The United States spends more per patient on the average than Minnesota does—$436.72 per patient nationally; $328.66 for Minnesota patients. National average for number of patients assigned to each employe is 6.2—in Minnesota it's 7.5.

Twenty-eight states are more overcrowded than Minnesota—twenty, including the District of Columbia, are less overcrowded. Seventeen have more patients per employe than Minnesota, while twenty-nine states, including the District, have fewer patients per employe, while two states are the same as Minnesota in this regard. Thirty-one states, including D. C., spend more per patient—seventeen spend less.

MEDICAL COSTS ANALYZED

A new study on "Comparative Increases In the Costs of Medical Care and the Costs of Living" is now off the press. Authored by Frank G. Dickinson, Ph.D., director of the American Medical Association's Bureau of Medical Economic Research, this study reports that living costs have skyrocketed at a much faster rate than physicians' fees.

The quantity of medical care received by Americans, according to Dr. Dickinson's findings, was two-thirds greater in 1946 than in 1939. He also found that the amount of care has increased faster than the number of physicians. The apparent increase in "output" of physicians is laid to the increasing use of technical assistants.

"Whether one examines the record of total expenditures of the American people for medical

care or the prices of significant items during recent years, he comes to the general conclusion that the American people have been fortunate in that the costs of keeping well have not risen as rapidly as the costs of living," Dr. Dickinson concludes.

Saint Paul, Minnesota

Texas Eye Swindler Sentenced to Five-year Term in Minnesota Prison

Re State of Minnesota vs. Elliott Wilkinson.

On May 14, 1948, Elliott Wilkinson, 54 years of age, Dallas, Texas, was sentenced to a term of not to exceed 5 years at hard labor in the Minnesota Prison at Stillwater, Minnesota, by the Hon. Karl Finkelnburg, Judge of the District Court at Winona, Minnesota. Wilkinson was sentenced following his plea of guilty, on the same date, to an information charging him with the crime of grand larceny in the second degree. That charge grew out of Wilkinson's arrest on May 9, 1948, by Winona, Minnesota, police officers after Wilkinson had swindled a Winona County farm woman out of $60 by falsely representing himself as an eye specialist from Chicago, Illinois, and further stating that the patient was afflicted with cataracts and that they must be immediately removed.

Wilkinson is an old-time eye swindler, who, with an accomplice, forfeited $8,000 in cash bail at New Ulm, Minnesota, in September, 1924, after both had been arrested for swindling a Brown County farmer out of $1,500. In the Brown County case, Wilkinson was not apprehended until 1932, at which time he was returned to New Ulm from Houston, Texas. On April 8, 1932, Wilkinson was sentenced by the Hon. A. B. Gislason, Judge of the District Court at New Ulm, to a term of not to exceed 5 years in the State Prison at Stillwater for grand larceny in the first degree, growing out of the $1,500 swindle perpetrated by Wilkinson and his accomplice in 1924. Wilkinson served at the Minnesota State Prison until November, 1933, at which time he was released and returned to Texas. In 1936, Wilkinson was arrested in Omaha, Nebraska, and removed to Norfolk, Virginia, where, on February 1, 1937, he pleaded guilty to using the mails to defraud. For that offense, Wilkinson admitted that he was sentenced to serve 7 years in the Federal Prison at Atlanta, Georgia. Wilkinson stated that he served in the Atlanta Prison until November 26, 1941, on which date he was transferred to the Virginia State Prison at Richmond, Virginia, to serve 5 years on the charge of swindling to which Wilkinson had pleaded guilty at Courtland, Virginia, just prior to his being sentenced in Federal Court at Norfolk, Virginia, in 1937. Wilkinson stated that he served in the Virginia State Prison until May, 1945. It is Wilkinson's claim that he was not arrested for any offense after being discharged from the Virginia State Prison, until he was arrested at Winona, Minnesota, on May 9, 1948. In explaining his method of operating, Wilkinson stated that he would seek out farm people, representing himself as an eye specialist, diagnose the case as cataracts and then proceed to extract a large sum of money from the patient. Upon receiving the money, Wilkinson stated that he would insert a liquid preparation in the eye and then show the patient a small piece of tissue paper, which Wilkinson represented as being the removed cataract. Just prior to his arrest at Winona, Wilkinson had attempted to swindle a Wisconsin farmer out of $1,400 in a similar fake eye operation. However, the farmer discussed the matter with his banker and was persuaded not to withdraw the money from his bank account.

The Minnesota State Board of Medical Examiners wishes to acknowledge the very fine co-operation received in this case from Sheriff George L. Fort of Winona County, County Attorney W. Kenneth Nissen, and the officers of the Winona Police Department. Wilkinson's prompt arrest at Winona was due, in large part, to the fact that the patient who had been swindled of the $60.00 reported the matter to the authorities, giving them an excellent description of Wilkinson which was published in the Winona *Republican-Herald.*

COR BILOCULARE

(Continued from Page 662)

cultures of the cardiac vegetations were not possible. Tiny Gram-positive cocci were found in pairs in the smears.

Summary

The case of a man, aged twenty-seven, dying as the result of congenital cardiac anomalies and their complications, including situs inversus subtotalis, cor biloculare, transposition of the aorta and pulmonary artery, pulmonary stenosis, absence of the ductus arteriosus, streptococci endocarditis on the atrioventricular valve leaflet, and evidences of chronic congestive heart failure, has been described.

Minneapolis Surgical Society

Meeting of February 5, 1948

Dr. L. Haynes Fowler, Presiding

CARCINOMA OF THE ESOPHAGUS

Resection, High Esophagogastrostomy

THOMAS J. KINSELLA, M.D.

Minneapolis, Minnesota

Carcinoma of the esophagus constitutes about 2 per cent of all carcinoma but is not ordinarly given the thought and consideration which its frequency would seem to warrant. Clinically, this condition usually manifests itself first by dysphagia. The patient frequently first chokes on a rather large morsel of food. Then he becomes more careful about chewing and has no difficulty for a month or two after which the same sequence may again be repeated. This may occur several times before medical aid is sought. The history may reveal no episodes of choking but only a gradually increasing dysphagia, first for solid foods and then for softer things, and only late for liquid foods. An average time interval of about six months elapses between the onset of the first symptoms and the establishment of the true diagnosis. Most of this delay may be the fault of the patient, but not infrequently the physician does not appreciate the significance of dysphagia and must bear an equal if not greater responsibility. Dysphagia, however slight, must not be passed over lightly; it should call for a thorough study, including not only x-ray examination of the esophagus but also esophagoscopy if the former does not reveal a cause for the difficulty.

Esophageal carcinoma occurs most commonly in individuals between the ages of forty to sixty years (75 per cent), perhaps slightly earlier in women than in men. The condition occurs four or five times as commonly in men as in women. The lesion may occur in the upper, middle or lower third of the esophagus. Two years ago, before this society, I presented some cases of carcinoma of the lower portion of the esophagus surgically treated by resection and esophagogastrostomy. This evening I wish to discuss carcinoma of the middle third of the esophagus and to present a case which illustrates well the problems and difficulties encountered in successful treatment of a lesion in this region.

The esophagus in the mid-third, which extends from just below the bifurcation of the trachea to the apex of the pleura, lies in a very confined space, hemmed in by the trachea and its bifurcation, the arch of the aorta, the vertebral column and the right pleural reflection. Tumors arising in this region tend to spread to the regional lymphatic nodes about the bifurcation of the trachea or to the cervical lymph nodes, or by direct extension to invade the trachea, the aorta, or the pleural cavity on the right. Their successful treatment is not only difficult but quite hazardous and not too frequently undertaken.

Until a few years ago, dilatation, gastrostomy or anterior esophagostomy were the only means available for the relief of patients suffering from this type of lesion. Repeated dilatation over a string may keep the lumen of the esophagus open to a moderate degree and enable the patient to swallow liquids and soft foods until metastases or extension terminate the picture. Gastrostomy at best is a very unsatisfactory answer to this problem. The patient cannot swallow or enjoy his food and is tormented by a profuse secretion of mucus from the esophagus above the obstruction which plagues him day and night. If carried out late when the patient is in a debilitated condition, the operative procedure alone may carry a mortality of approximately 50 per cent. Resection of the local lesion with creation of a cervical esophagostomy, later to be connected to a gastrostomy opening by an external tube of rubber (the Torek operation), or by creation of a skin tube of the Gilles type, is at the best a very unsatisfactory procedure.

Primary resection of the offending lesion with mobilization of the stomach and primary anastomosis between the esophageal stump and the stomach high in the chest presents a much better answer to the problem, but is fraught with technical difficulties which increase as the apex of the pleura is approached. The patient whose case history I am presenting this evening illustrates these difficulties well, for his lesion lay very high and the reconstruction necessary involved making an anastomoses between the lower end of the cervical esophagus and the elevated stomach, a technical problem whose solution was considerably facilitated by the use of some special miniature de Martel clamps which we had made for this specific purpose.

Case Report

S. G., a man, aged fifty-seven, was admitted to St. Mary's Hospital, October 29, 1947. His general health had always been good until about seven years previously when he developed a carcinoma of the larynx which was successfully treated by total laryngectomy. An excellent result was obtained, leaving him with a permanent suprasternal tracheotomy. He had remained in good health subsequently and had reported to his original surgeon every six months for a re-check since that time.

About June, 1947, he began to have slight difficulty in swallowing, particularly for solid foods. As this did not improve he reported again to his original surgeon who found the cause of his difficulty to be an obstruction in the esophagus just above the arch of the aorta as demonstrated on the barium esophagram. Esophagoscopic examination did not visualize any tumor tissue which could be biopsied to establish a definite diagnosis. The possibility of primary carcinoma was

considered, but because of the previous carcinoma of the larynx and in the absence of a demonstrable ulcerative lesion it was considered logical that the obstruction was the result of possible metastatic carcinoma in the lymph nodes in the upper thorax. Surgical exploration was not recommended. Esophageal dilatation with sounds was carried out at once, repeated eight days later and again a month later. Subsequently, in September and October he was seen by Dr. Paul Boman of the Duluth Clinic, who also made an additional esophagram which revealed a localized obstruction slightly above the level of the arch of the aorta, of a character suggesting a primary esophageal lesion rather than extrinsic pressure obstruction. Dysphagia of moderate degree persisted in spite of the repeated dilatation, with progressive weight loss totaling 30 pounds. There was no pain nor cough, nor could any lymph nodes be palpated.

Physical examination revealed a well-developed, well-nourished sturdy individual, weighing 192 pounds in spite of his recent weight loss. His complexion was very florid. There were no palpable lymph nodes. There was a tracheotomy tube in the suprasternal region in a well-healed vertical scar from previous total laryngectomy. The blood pressure was 150 systolic and 100 diastolic in millimeters of mercury. The pulse was 88 per minute. The temperature was 99.2 degrees. The remainder of the physical examination was negative.

Laboratory examination revealed a hemoglobin of 102 per cent, red blood count of 5,490,000 cells per cubic millimeter and white blood cells 6,050 for each cubic millimeter. Differential count showed 70 per cent polymorphonuclear leukocytes and 30 per cent lymphocytes. The bleeding time was 4 minutes, coagulation time 4 minutes and 30 seconds. The blood was group 4.0, Rh negative. Total blood proteins were 7.0 grams, with 5.5 grams serum albumen and 1.85 grams of globulin. The urine was acid, the specific gravity was 1.014. There was no albumen nor sugar, and only a few epithelial cells were found in the sediment. An electrocardiogram revealed only a left axis deviation. Roentgen examination of the chest revealed the heart and aortic shadows to be normal in size, shape and position, with no broadening of the mediastinum. The lung fields were within normal limits. A lateral view of the thorax revealed no masses suggestive of mediastinal lymph node enlargement. Esophagoscopic examination was carried out October 20, 1947, by Dr. Kenneth Phelps. Only a conical narrowing of the esophagus was revealed in the involved area. It was lined with normal appearing mucosa and showed no tumor from which biopsy material could be obtained. There was no evidence of extrinsic displacement of the esophagus.

A tentative diagnosis of primary esophageal carcinoma was made and the condition and its possibilities and difficulties fully discussed with the patient and his medical relatives. Exploratory thoractomy in the hope of carrying out a resection was recommended.

Operation was carried out October 31, 1947, at St. Mary's Hospital, Minneapolis, under intravenous pentothal and curare (Baird's solution), with the intratracheal tube in place, through which 50 per cent oxygen and nitrous oxide was administered by Dr. Joseph Baird. A total of 3 grams of pentothal and 120 units of curare were used. With the patient in right three-quarters prone position, a wide, oblique, posterior incision was made with resection of a wide segment of the posterior sixth rib. The pleural cavity was opened and the thorax explored. Exploration of the hilar region of the lung revealed no enlarged or palpable lymph nodes present. The mediastinum was opened inferior to the arch of the aorta, and the exploring finger revealed no enlarged lymph nodes and no tumor mass until the finger was inserted well in front of the arch where the lower border of an apparently intrinsic tumor mass could be palpated with the tip of the finger. The mass was well above the upper border of the arch of the aorta and confirmed our impression that this was an intrinsic carcinoma and not an obstruction resulting from metastatic nodes. The upper mediastinum above the arch of the aorta and posterior to the left subclavian artery was opened, and again no metastatic nodes were palpated. The tumor seemed to be movable, but because of its very high position it was realized that difficulty would be encountered in reconstruction which must follow any removal. The possibilities and dangers of its removal were then discussed with medical relatives present at the operation and attempt at resection was decided upon.

The thoracic incision was then extended, cutting two ribs above and one below the previous site. The mediastinal pleura was split from the aortic arch to the diaphragm, the lower esophagus mobilized and a traction tape placed about it. The vagus nerves were sectioned, and the esophagus was dissected free from the arch of the aorta to the diaphragm. The diaphragm then was split from the hiatus laterally nearly to the chest wall, the stomach mobilized on both lesser and greater curvatures, keeping well away from the border of the stomach, to preserve the anastomic arches, freeing the stomach down nearly to the duodenum, being careful to preserve the right gastric and the right gastroepiglottic vessels. The left gastric artery and left gastroepiglottic and the vasabrevia to the spleen were all sectioned and ligated. This allowed the stomach to come freely into the chest. Dissection was then carried up along the esophagus behind the arch of the aorta, separating the esophagus from the aorta and from the adjacent bifurcation of the trachea, until the tumor mass was reached. This was then dissected up as far as possible on all sides with the finger, clamping and ligating any cord-like attachments in order to control the blood supply from the aorta to this area of the esophagus.

A special small 2-inch de Martel type of clamp was then placed across the esophagus, just below the arch of the aorta, and closed. The esophagus then was grasped with a special Buie type of hemorrhoid clamp just distal to the de Martel clamp and the esophagus sectioned in between with a scalpel. Two similar Buie clamps were then placed across the esophagus at its junction with the stomach and the esophagus cut across between them, thus removing the lower thoracic esophagus. The stomach defect was then closed with a continuous chromic catgut suture for hemostasis and this defect inverted into the stomach and the closure line reinforced with interrupted silk sutures. A heavy silk suture attached to the small de Martel clamp was then passed around the arch of the aorta and brought out through the mediastinal pleural opening above the arch and posterior to the subclavian artery. Then the esophagus, with the clamp attached, gradually was brought around the aortic arch and out through the pleural opening into the pleural cavity above the arch.

By more finger dissection the esophagus and its tumor was then freed of all attachments, none of which were dense, and delivered into the upper part of the pleural cavity. This was accomplished with considerable difficulty because the tumor was about 4 centimeters long and extended up beyond the line of pleural reflection, so that in order to deliver it into the thorax it was necessary to mobilize the esophagus well above the tumor and to pull it down into the thorax. This involved mobilization of the lower end of the cervical esophagus. Firm traction was then applied to the de Martel clamp to bring the cervical esophagus into the upper chest, and two additional de Martel clamps were placed adjacent to each other above the upper limits of the tumor and closed, crushing across the esophagus. The esophagus was then cut between these two clamps, and the tumor removed from the chest. Closure of these clamps was accomplished with some difficulty because the ordinary de Martel-Wolfenson closure clamp is too large and cumbersome to be used high in the

thorax. For this job we used a specially devised closing forceps made from an ordinary pair of pliers, which grasped and closed the two clamps quite satisfactorily in this limited space.

The upper de Martel clamp which was on the lower end of the cut esophagus then was grasped by the long de Martel clamp holder and traction exerted upon it, pulling the esophagus down in order to start our anastomosis. In order to facilitate this, the clamp holder with attached clamp was rotated posteriorly as traction was applied, thereby exposing the anterior wall of the esophagus. A series of five interrupted mattress sutures were placed through the muscular wall 5 or 6 millimeters proximal to the crushing clamp and the needles left attached to these long silk sutures. An area was then selected on the posterior wall of the stomach, slightly below its upper end and a small button of gastric wall excised. All bleeders were controlled by ligature of fine silk, and all stomach contents aspirated from the organ to prevent soilage in the operative field. The stomach was then elevated to the apex of the pleura which it reached without any tension. The previously placed sutures were completed through the gastric serosa and muscularis, and were tied up, thereby approximating and completing the first row of sutures. The placing of these sutures and the typing was greatly facilitated by the traction which could be maintained on the de Martel clamp still in position on the lower end of the esophagus. Had this clamp not been left in position the esophagus would have retreated up into the neck and prevented anastomosis. Traction might also be maintained by pulling on the esophagus and tumor, but only with greater chance of contamination and more technical handicap because of the very limited space.

A similar set of sutures was placed through the muscular wall of the esophagus above the clamp on the posterior aspect. The needles were left attached again and tagged to be used later to complete the anastomosis. This set was placed again as a precautionary measure for holding traction on the esophagus in case it attempted to retreat after taking off the de Martel clamp. The de Martel clamp then was removed from the esophagus. No attempt was made to excise the crushed portion, a techincal point which we always insisted upon in lower anastomoses because of the poor esophageal blood supply. The mucosa of the esophagus and the adjacent mucosa of the gastric defect were then sutured together in a second anterior row of interrupted mattress sutures of No. 3 silk. A series of five sutures was placed. A nasal suction tube then was passed up the esophagus into the muoth where the anesthetist retrieved it and pulled up the greater length of the tube, leaving only enough to extend down to the pyloric region of the stomach.

A series of five interrupted mattress sutures of silk then were placed in the mucosa of stomach and esophagus, approximating these two layers as the first row of the posterior suture in the anastomosis. The sutures previously placed posteriorly in the esophagus now were completed through the adjacent serosa and muscle of the stomach, the second posterior row finishing the anastomosis. This anastomosis was accomplished only with the greatest difficulty because of its location high in the chest and the extremely cramped quarters which made the placing of all sutures very, very difficult. At best we must concede that the anastomosis was not a perfect one and that leakage might be anticipated. The stomach then was sutured to adjacent pleural structures, with a series of interrupted chromic catgut sutures in order to remove all tension from the anastomotic line. The diaphragmatic defect was then closed by imbrication using interrupted No. 2 forty-day chromic catgut, leaving a fair sized hiatus above the elevated stomach and then suturing the cut edge of the diaphragm to the adjacent stomach wall. The pleural cavity then was washed out thoroughly with copious quantities of salt solution. Five intercostal suction catheters were inserted through the chest wall with their tips placed in strategic locations where fluid might be expected to form or to pool and three grams of sulfathiazole and sulfanilamide dusted around the anastomotic site and in the adjacent pleural pockets. During the whole procedure the lung was reinflated repeatedly in order to prevent permanent atelectasis.

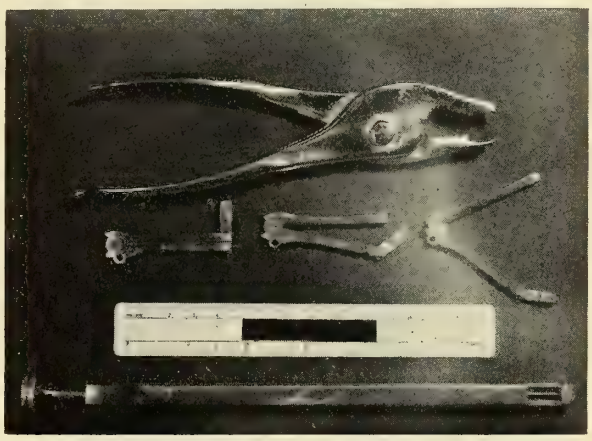

Fig. 1. Miniature De Martel clamps, closing forceps, and holding clamps.

The chest wall then was closed in layers as in any other thoractotomy, after inserting about 300 cubic centimeters of salt solution into the chest to prevent clotting of any oozing blood which might plug our suction catheters. The patient tolerated the extensive and very prolonged (fourteen hours) surgical procedure very well. While on the table he received a total of 6 liters of blood, 500 cubic centimeters of normal saline and 500 cubic centimeters of 5 per cent dextrose in normal salt solution. He was returned to this bed in good condition and placed in an oxygen tent. Continuous suction was applied to the stomach tube and continuous suction at minus 20 centimeters of water applied to the intercostal catheters in order to remove all fluid from the pleural cavity and to keep the lung expanded. Penicillin and sulfadiazine were administered postoperatively and adequate amounts of fluid given subcutaneously and intravenously for the first seven days, during which time nothing was allowed by mouth. He developed a great deal of mucus in his chest postoperatively but this was removed successfully by using a suction catheter through the tracheotomy opening. After the fifth postoperative day, small amounts of water were inserted through the nasal catheter as soon as it was evident that the pylorus had opened up from the effects of the vagotomy. Increasing amounts of liquids were then given through the catheter until after the seventh day when liquids were given by mouth.

The patient was discharged from the hospital on November 25, 1947, ambulatory, on his twenty-sixth postoperative day. On November 20, 1947, his twentieth postoperative day, the anastomotic orifice was dilated over a string up to a No. 38 French dilator in order to be sure that the lumen of the anastomosis was adequate. There is a very considerable tendency for stenosis to develop in the anastomotic site, particularly where constructed under considerable technical difficulty, so he may have to be dilated on a number of occasions subsequently. His condition has remained good since that date, with only the usual discomfort which accompanies distention of the stomach in the chest and some cutting down of his breathing space by such pressure.

Of course, he has also had the usual gastrointestinal disturbances incident to the vagotomy necessary in such a procedure. Recently Dr. Boman wrote that he is feeling very well, swallowing freely, and that a No. 46 French dilator may be massed without meeting obstruction, so the anastomosis has been kept at full lumen. The illustrations will give a good idea of the original lesion, the position of the stomach in the thorax, and the location of the anastomosis at the level of the sternoclavicular joint.

Fig. 2. Postoperative view of a high esophagogastrostomy.

The de Martel clamps which we have used in the anastomosis were especially devised for this procedure. They are identical in form and line with the larger de Martel clamps but are only 2 inches in length, which is adequate for the ordinary undilated esophagus. Such clamps offer distinct advantages in this type of surgery. In the first place they do not slip off the crushed esophageal stump and are therefore safer than an ordinary ligature which has been used as the esophagus is passed behind the aortic arch, as is necessary in this procedure. Secondly, by the use of this clamp it is possible to use traction in the esophagus to pull it down and hold it until sutures are placed to maintain it in position. Thereby, a higher anastomosis is made possible than could be done without the use of this device. It may be used also to advantage in similar situations in other places, such as for control of the esophagus in total gastrectomy, or even in the colon, deep in the pelvis, where an end-to-end anastomosis is to be made.

This case report illustrates what can be done in the way of total resection of the thoracic esophagus and re-establishment of intestinal tract continuity by anastomosis of the cervical esophagus to the elevated stomach. The freely mobilized stomach easily reaches the apex of the pleura without tension, and I am sure that the stomach or a portion of it may be brought even into the neck, where an anastomosis at a higher level may be accomplished perhaps with less difficulty than the present one.

Discussion

Dr. Magney, Duluth: I am not acquainted with the modern procedure, but I recall the good old days when we dilated carcinomas of the esophagus. During my internship at the Ancker Hospital I prevailed on Dr. Ancker to purchase a dilating outfit, which in itself was quite an accomplishment. I was saved from embarrassment by the patient's inability to swallow the string. That night the patient died suddenly due to rupture of the aorta which the cancer had invaded.

Dr. R. E. Hultkrans: What percentage of all carcinomas of the gastrointestinal tract does carcinoma of the esophagus constitute?

Dr. Schlemenson: I should like to ask Dr. Kinsella what his experience has been in the use of radium therapy in the treatment of carcinoma of the esophagus.

Dr. Kinsella: Carcinoma of the esophagus constitutes about 2 per cent of all carcinomas; carcinoma of the lung, 12 to 15 per cent; carcinoma of the colon, about the same, 15 to 20 per cent.

Radiotherapy has not accomplished much with these patients. Most of these tumors are squamous cell epitheliomas. This area of the gastric mucosa does not respond well to x-ray therapy. You can maintain a lumen by use of a string.

REPORT ON A TOUR OF EASTERN SURGICAL CLINICS

ARNOLD J. KREMEN, M.D.

Minneapolis, Minnesota

It is a deep pleasure to be able to recount to this audience my experience on a tour to a number of the outstanding surgical clinics in the East and Midwest. Before proceeding, I wish to acknowledge my gratitude and appreciation to Dr. Owen H. Wangensteen and Dean H. S. Diehl and the University of Minnesota for having made this trip possible. The purpose of my trip was principally to investigate recent trends and developments in clinical surgery and research, to examine the teaching programs of the various schools and to observe the physical facilities, principally of operating suites that might advantageously be put to use in our own hospital.

During such a trip one forms a number of impressions, one of which has remained throughout the trip. To me the lack of productiveness of the large hospitals over 1,000 beds was quite striking. They seemed to get out of hand, so to speak, and lacked a unity of purpose or personal direction and interest. Some of the smaller hospitals, on the other hand, such as Massachusetts General Hospital of Boston and Strong Memorial Hospital of Rochester, New York, where the direction of the service was more closely supervised and the staff was a more closely knit group, appeared

to be achieving a greater over-all contribution to medicine. I have the impression that the optimal size for a teaching hospital is somewhere between 600 and 800 beds.

Time will not permit a detailed account of each institution, but I shall try to relate to you the highlights of each clinic as they appeared to me.

Tulane Medical School, New Orleans

Drs. Champ, Lyons and DeCamp are enthusiastic about preparing poor-risk patients for major surgery by multiple blood transfusions. They have written about "chronic shock" and have pointed out the contracted blood volume which occurs as an accompaniment of the malnourished state. Of most importance in this regard, they feel, is the total hemoglobin deficit. Correction of this plus the contracted blood volume by multiple whole blood transfusions during the preoperative period of preparation is their principal concern.

Dr. Alton Ochsner is quite partial to the use of cotton as a suture material. He uses it by preference in almost all cases and feels it has less tendency to be the cause of granulomas and to sequestrate than does silk. On the problem of thrombophlebitis, Dr. Ochsner stated his position is midway between Rochester, Minnesota, and Boston, Massachusetts. With a twinkle in his eye he said, "We ligate those that need ligation and give anticoagulants to those that need anticoagulants." I couldn't get him to expand on the problem much beyond that. He does feel that procaine sympathetic blocks have a definite therapeutic role in treatment of acute thrombophlebitis. He did not feel that vagotomy was proving its claims in the treatment of ulcer and stated that, in his opinion, gastric resection was still the treatment of choice in those ulcer patients who required surgery.

Dr. DeBakey stated that he was disappointed with most tests at present which attempt to portend the response to sympathectomy. As a result he has been extending lumbar sympathectomy to all patients with vascular insufficiency of the lower extremity. There have been a number of gratifying results in patients in whom the outlook before operation was almost hopeless. Also in those who subsequently required amputation it was possible to perform the amputation at a lower level than would have been necessary otherwise.

Barnes Hospital, Washington University, St. Louis

Drs. Graham and Burford are of the opinion that palliative pneumonectomies are not worthwhile. In contradistinction to the gastrointestinal tract, where it is well recognized that resection of neoplasms even in the presence of unresectable metastasis is a worth-while procedure, in that it extends the patient's life and makes him more comfortable, in carcinoma of the lung such palliation or prolongation of life has not resulted, in their experience. Dr. Graham stated that he was not aware of any successful pneumonectomy in a patient past seventy years of life. Of 1,000 thoracotomies that they have done for carcinoma of the lung, they have been able to resect 22 per cent of the cases.

Because of Dr. Graham's special interest in thoracic surgery, they have a superb chest service. The general surgical services, on the other hand, although of high calibre, did not appear to be on a par with the chest service.

Dr. Robert Elman is continuing electrolyte balance studies in surgical patients. Of interest is his finding that sodium chloride requirement in the average patient, without loss of intestinal content, is in the area of 2 grams per day.

Vanderbilt University, Nashville

Of special interest to me at the Vanderbilt Hospital was an exceptional sterile supply suite. It consisted of two large rooms completely separated by a partition which contained the autoclaves. These opened at both ends. In one room all unsterile materials were processed and put into the autoclaves. The sterile materials were removed from the other end of the autoclave in the second or sterile room. Hence all materials in one room were unsterile, and in the other room on the other side of the partition, all materials were sterile. The surgical service there is an excellent one under the direction of Dr. Brooks and associates, MacSwain and Daniels. Dr. Hahn has been doing some very interesting work with radioisotopes. They are in the advantageous position of being close to Oak Ridge and have done some of the fundamental work with radioiodine and gold.

Johns Hopkins Hospital, Baltimore

Unfortunately, Dr. Blalock was in England at the time of my visit so I missed the opportunity of visiting with him and seeing him operate. Dr. Longmire was carrying on in his stead and made the Blalock and portocaval operations look amazingly simple. Much of the experimental work in progress at the time related to problems pertaining to the cardiovascular system. On the general surgery service they were doing total gastrectomies routinely on all cases of carcinoma of the stomach. They admit it to be an experimental venture to see if the more radical operation applied to all cases, rather than to a selected few, will extend the cure rate.

University Hospital, University of Pennsylvania, Philadelphia

Dr. Ravdin and his associates have one of the outstanding clinics I had the opportunity of visiting. The clinical work was excellent; the research program and facilities were eminently good. Drs. Parkins and Rhode, by using a polythene tube in the vena cava of dogs, have maintained a continuous intravenous infusion for forty days. They administered 50 per cent glucose at the rate of 20 c.c. per kilogram per day (the equivalent of 1,500 c.c. to a 70 kg. man) over a twenty-four hour period without observing glycosuria or thrombosis. When given into a vein with a large enough flow, sufficient dilution of the glucose takes place immediately to prevent damage to the vessel.

From bacteriological studies of bowel content, Dr. Zintel and associates think that streptomycin given

orally in amounts of 1 gram daily in divided doses for four to six days is the most effective agent available in reducing the bacterial count of the stool.

New York Hospital, Cornell University, New York

In Dr. Ephriam Shorr's laboratory, Dr. Wheadon has been carrying on some very interesting studies relating to convalescence. He has noted a fairly marked nitrogen loss, occurring in normal people on adequate diets, as a result of the immobilization incident to going to bed. This began on the fourth day and continued up to the tenth day. Concommitantly, he noted an increased urinary calcium excretion unassociated with an increased citrate excretion which would tend to hold the calcium in solution. In addition the pH of the urine tends to rise further, increasing the tendency for the calcium to precipitate from solution.

In the operating suite they have installed a recovery ward where all postoperative patients are kept up to twelve hours or until they are awake, stabilized and responding. Two nurses, under the direction of the anesthesia and surgical house staff, look after the patients and give whatever supportive measures are necessary. They have found this arrangement to be of considerable assistance in relieving the load of nursing care on the surgical wards, and to offer better immediate postoperative care for the patients.

New Haven Hospital, Yale Medical School, New Haven

Of special interest at Yale was the work Dr. Darrow is doing on electrolyte balance. He has shown that in the diarrheas of infancy there is a considerable loss of potassium from the body which should be replaced. Furthermore, in some dehydrations there may be a shift of sodium ions into the intracellular compartment with loss of potassium from the cell. One of the things necessary to correct this situation may be administration of potassium ions. There appears to be a continuous loss of potassium from the body which normally is relatively small and probably of no major importance for a period of several days. However, over a longer period of negative potassium balance one should strongly consider replacing potassium deficits. The kidney does not appear to be able to selectively retain potassium as it does sodium. On the basis of Dr. Darrow's work, one's outlook on fluid balance problems should probably include the intracellular compartment and its requirements, in addition to the conventional concepts of extracellular and blood compartments that have absorbed the attention of most clinicians to date.

Harvard Medical School, Boston

The organization of the medical facilities of Boston under the direction of Harvard Medical School seems to me to be an outstanding administrative achievement. Four units, Massachusetts General, Beth Israel, Children's and Peter Bent Brigham Hospitals, are each autonomous but responsible to the over-all direction of the Harvard faculty. Each carries out its teaching functions, research program and clinical work independently but are bound to the medical school for top level policy, for leadership in maintaining standards of practice and to further the over-all teaching program. Each hospital gives up an iota of authority to the Harvard Medical School, but in return they gain tremendously in prestige in the community and on a national scale throughout the profession.

At Massachusetts General, considerable work is in progress under direction of Drs. Cope and Moore using radiosotopes in studies of intracellular metabolism. At Beth Israel Hospital, Fine and Seligman are continuing their excellent work on shock. They have recently demonstrated that one of the factors determining reversible or irreversible shock is the status of the hepatic circulation. By cross circulation experiments whereby they maintained an adequate hepatic circulation, animals would withstand procedures which in control preparations uniformly produced irreversible shock.

Dr. Swenson at Children's Hospital related some interesting esophageal work going on there. He has been able to resect 50 per cent of the thoracic esophagus in dogs, mobilize the remaining segments and do successful end-to-end anastomosis. In tracheo-esophageal fistula he is regularly doing primary anastomosis. On some of the earlier cases upon whom cervical esophagostomies had been performed, he has reoperated, mobilized thoracic and cervical esophagus and effected end-to-end anastomoses. In Hirshsprung's disease, Dr. Swenson feels the primary abnormality is a spasm in the area of the rectosigmoid. This can be demonstrated by barium enema if given slowly. He has had some encouraging results by resection of the involved area of sigmoid and rectosigmoid and doing a low anastomosis.

Strong Memorial Hospital, University of Rochester, Rochester, N. Y.

The medical school at Rochester was among the best of the schools visited. The beneficent influence and direction of Dr. George Whipple pervades the entire atmosphere. He has been dean and professor of pathology since the school was founded in 1925, and much accomplished there has been due to his wise leadership and foresight. The group at Rochester have been leaders in investigative work on protein metabolism. They feel that intravenous plasma protein is utilized in the general protein economy of the body. Recently, they have maintained a dog in nitrogen equilibrium for ninety-two days, during which time the only protein intake was intravenous plasma transfusions. Proteinuria developed after about a month on intravenous feedings, but nonetheless, the animal did not go into a state of negative nitrogen balance. They feel that there probably is a renal threshold value for protein, as is well known for other materials and when this threshold is exceeded proteinuria results. Apparently no organic renal lesions occurred as a result.

Dr. Basset mentioned the use of testosterone to promote nitrogen retention. In addition, it appears to promote water retention. On the other hand, in starvation a decreased excretion of 17-testosteroids has been noted, which may suggest a decreased testosterone formation under those conditions.

Clinically, their interests have been many and varied. Recently, they have gained an experience in doing sympathectomy for hypertension by the transpleural route and seem to prefer it over the other approaches.

Buffalo General Hospital, University of Buffalo, Buffalo

Dr. John Paine, formerly of our own school, recently has assumed the duties of professor of surgery at Buffalo. John is doing a splendid job of reorganizing the service and expanding the laboratory facilities. He has performed successfully the first patent ductus ligation and Blalock operations done in Buffalo. Dr. Paine is well and happy and would like to be remembered to all his friends in this audience.

University of Michigan, Ann Arbor

At Ann Arbor a number of interesting projects are in progress. They have been doing lumbar sympathectomies on a large group of patients with arterial vascular insufficiency of the lower extremities. Their views and findings are quite similar to those of DeBakey in New Orleans related earlier in this paper. In the group of diabetics where the outlook for vascular insufficiency has been exceptionally grim, they have experienced some encouraging results.

They are continuing studies of fluid and electrolyte balance and have also come to appreciate that potassium losses over a period of time may be of sufficient consequence to require replacement.

After a trip such as I have outlined to you this evening, one returns home with mixed feelings. One is full of new ideas, one sees famous institutions and men, one gets to see the surroundings from which so many of the contributions to medical literature and practice arise. I believe that in the future, after such an experience, one will be better able to evaluate these contributions critically and judiciously. Certainly as a result of even a momentary familiarity with their source of origin, articles originating from these institutions will mean much more to the visitor. Such is the value of travel. But it also has another virtue. On gaining a familiarity with distant places having a certain aura of fame and glamour associated with their name, one returns home to experience a sense of contentment and satisfaction with one's own workshop and colleagues.

VOLVULUS OF THE SIGMOID

(Continued from Page 653)

colostomy opening. Later, an anastamosis between these two parts of the sigmoid may be made. This procedure would seem to have some merit.

Recently, two cases of volvulus of the sigmoid colon have been operated upon by me in which there was evidence of minimal gangrene of the bowel. Both patients were in good condition at the time of operation. A primary resection of the gangrenous bowel was performed with end-to-end anastamosis, using a running inner row of 000 chromic catgut and two rows of interrupted 000 silk sutures. The walls of the cut ends of the sigmoid were edematous but were thick and hypertrophied; it was felt that the anastomosis could be safely made. The patients made an uneventful recovery, and both were discharged from the hospital within ten days after the primary resection.

In cases of acute obstructions of the large bowel, it is realized that it is best to decompress the bowel before doing a primary resection. However, in volvulus of the sigmoid colon our experience would indicate that if the patient is in good condition and the colonic distention is not too great, a primary resection and anastamosis of the sigmoid may be carried out successfully.

Comment

It is realized that patients with volvulus of the sigmoid are usually elderly and debilitated, and are poor risks because of this condition. Such patients have been treated in the past by a Mikulicz type of exteriorization resection which, as has been pointed out, entails certain inherent risks. The use of this procedure in this type of obstruction accounts in part for the high operative mortality. The following outline of therapy is suggested:

1. If gangrene at the site of torsion and serious bowel damage can be ruled out, proctoscopy and passage of a tube to deflate the distended sigmoid will be carried out. The tube will be left in site for a few days, after which the volvulus of the sigmoid loop will be resected and an end-to-end anastamosis performed.

2. If the above complications are present or intubation per rectum is not possible, the patient should be explored. Rather than do a Mikulicz exteriorization and resection, the gangrenous bowel will be resected, the distal stump of the sigmoid inverted and buried, and the proximal part brought out as a colostomy opening. If the patient is in good condition, the bowel shows no or slight gangrene, and the distention is not too great, a primary resection with end-to-end anastamosis of the sigmoid may be considered.

Minnesota Academy of Medicine

Meeting of February 12, 1948

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Thursday evening, February 12, 1948. Dinner was served at 7:00 p.m. and the meeting was called to order at 8:00 p.m. by the president, Dr. T. A. Peppard.

There were thirty-three members and three guests present.

Dr. E. M. Hammes read the following Memorial to Dr. Alexander R. Hall, and a motion was carried that this be spread on the records of the Academy and a copy sent to Mrs. Hall.

ALEXANDER RITCHIE HALL, 1874-1947

Alexander Ritchie Hall died suddenly at home Thanksgiving morning, November 27, 1947, while preparing to be host at the family dinner, which he always enjoyed so much. He was seventy-three years old.

Dr. Hall was born April 25, 1874, at Washington, Ontario, Canada, the son of Thomas and Agnes (Bobson) Hall. He attended common and high schools at Washington, St. Catherine and Woodstalk Collegiate Institutions, all in Ontario, Canada.

Dr. Hall was graduated from McGill University Medical School, Montreal, in 1902. He was interned at Montreal General Hospital after which he went to England for postgraduate work qualifying to practice as M.R.C.S. and L.R.C.P. in 1903. He came to Saint Paul in 1904 to enter medical practice with offices in the Moore Building, Seven Corners. He was associated with the late Dr. Arnold Schwyzer for four years, from 1904 to 1908. He was one of the original members of the Miller Clinic, also a captain in the English Army.

He was a member of the Ramsey County Medical Society, the Minnesota State and the American Medical Associations, a Fellow of the American College of Physicians and a member of the Minnesota Academy of Medicine, of which he was president in 1935. His thesis was given on "Status Lymphaticus," December 6, 1911, and his address as retiring president was on "Hypoglycemia." Both papers were published. He was also a member of the Minnesota Society of Internal Medicine, the Saint Paul Clinical Club, Delta Upsilon and Nu Sigma Nu fraternities. He served as chief of "A" Medical Service at Ancker Hospital for many years, with teaching arrangements with the University Medical School, and served as chief of staff in 1933.

Dr. Hall retired from practice about a year ago, having previously suffered a cerebral hemorrhage, but he kept up his visits to Ancker Hospital and was loved for his kindly teachings by many groups of interns who admired him greatly.

Alec Hall enjoyed the outdoors, being an ardent hunter and fisherman, and was most considerate of his friends on these many outings.

Dr. Hall was married in 1928, and his widow, Maude Perry Bowman Hall, survives him, as do a brother, Oliver Hall, and a sister, Dr. Jean Hall, both of Canada.

Dr. Hall was a kindly gentleman, a fine friend and an able physician. The following precept, attributed to the American Quaker, Stephan Grellet, certainly could have been his:

"I shall pass through this world but once; any good thing therefore that I can do or any kindness that I can show any human being, let me do it now. Let me not defer or neglect it for I shall not pass this way again."

His passing leaves a definite memory of such a man.

The scientific program followed.

Dr. Moses Barron read a paper on "Streptomycin in Tuberculosis." Two cases were reported, and one of the patients was presented at the meeting.

STREPTOMYCIN AND TUBERCULOSIS

MOSES BARRON, M.D.
Minneapolis, Minnesota

When Dr. Waksman and his associates discovered streptomycin, they gave to the world the first drug which has proved capable of altering the course of human tuberculosis. They found that this antibiotic was also effective against many Gram-negative bacteria. In a large series of cases treated with streptomycin, satisfactory results were obtained in the treatment of (1) urinary infections and infections with bacillus coli, proteus, pyocyaneous, and Friedlander's bacillus, (2) influenzal meningitis, (3) tularemia, (4) brucellosis, and (5) a miscellaneous group. Its effectiveness in many of the above infections has proven to be as great as that of penicillin in the pneumonias.

About a year after its discovery, Drs. Hinshaw and Feldman of the Mayo Clinic reported that streptomycin had a strong suppressing effect on tuberculosis, both of animals and of humans. It has proved effective in peritonitis following ruptured appendices or other ruptured viscera. One of the difficulties encountered with streptomycin is the early development of bacterial resistance to the drug, especially in tuberculosis. Its effect on tuberculous infections is at times very dramatic, especially in the acute hematogenous and exudative types. Very favorable results have been obtained in from 10 to 20 per cent of cases of tuberculous meningitis. Chron-

ic fibrocaseous types of pulmonary tuberculosis with cavitation do not respond. Resistant strains seem to appear in from four to eight weeks following the onset of the treatment. Toxic effects are usually mild in short courses of treatment, but in prolonged courses the more serious of these is the development of vestibular dysfunction, with vertigo, dizziness, and on occasions even deafness. This toxic effect occurs mostly from the use of large doses of from 2 to 4 grams daily over periods longer than three or four weeks. The vertigo may persist indefinitely, and when recovery occurs it is usually through some compensatory mechanism. The second rather severe complication is nephropathy. This may proceed to renal insufficiency. However, the renal damage which develops in about 3 per cent of the cases treated seems to be reversible, and usually goes on to healing and complete restitution after discontinuance of the drug. Streptomycin seems to be of little or no value in virus infections. In many cases of pulmonary tuberculosis the beneficial results are very striking. The sedimentation rate is decreased, positive sputa are converted into negative ones, fever is lowered or abolished, and the cough is reduced and often stopped. There may be a progressive gain in weight. Recent experience has shown that a dosage of 1 gram a day is just as effective as the larger doses previously used, and at the same time toxic effects are almost eliminated. It must be borne in mind that it is too early to claim cures of tuberculosis with streptomycin, no matter how good the results may be. We can only state that the cases treated have been arrested, and that the results seem better than with the methods previously used. However, the old routine of rest, diet and pneumothorax is still necessary in the management of most cases of tuberculosis.

I have had the opportunity of studying two cases of tuberculous peritonitis which have responded exceedingly well to streptomycin.

Case 1.—Mrs. N. J., aged thirty-nine, was admitted to the Asbury Hospital on October 17, 1946, with complaints of abdominal distention of about two months' duration and obstruction of the bowels of about two weeks' duration. During the previous month she had had fever, dyspnea, anorexia, malaise and insomnia.

Past History.—At the age of twenty-one she became sick with what was diagnosed pneumonia. She developed a pleurisy in the right chest. This was aspirated, and tubercle bacilli were found in the fluid. She made a complete recovery from the infection except that the right chest gradually seemed to shrink and became quite flat. She became entirely well and remained well up to the present illness. At no time did she have any cough. About October 5, 1946, she developed pain in both legs, as well as in the elbows and knees; her fever at times rose to 102°, and the abdomen slowly swelled. She developed progressive dyspnea. From about October 10 on, she became practically bedridden because of weakness and shortness of breath. She became markedly bloated and had pains and tenderness in the abdomen. She was sent to the Asbury Hospital by her doctor on October 17, 1946, with a diagnosis of intestinal obstruction.

Physical Examination.—The patient was very uncomfortable because of shortness of breath and tightness of the abdomen. Temperature was 102.6°, pulse 125, respirations 28 to 30; the blood showed hemoglobin 97 per cent, white blood cells, 7,700; and the urine showed a trace of albumin, a few pus and red blood cells. Blood cultures were negative. On examination, the right chest was greatly retracted, flat, and immobile; numerous loud coarse râles were present throughout the right chest, and breath tones were very distant. The left chest was entirely negative. A diagnosis of chronic adhesive tuberculous pleuritis and tuberculous peritonitis was made.

Paracentesis of the abdomen yielded 2,000 c.c. of a turbid light brown fluid. It showed 890 cells per cubic centimeter with 76 per cent mononuclears, 24 per cent polymorphonuclears, and there were 4.3 grams protein per liter. No tubercle bacilli were found. An x-ray of the chest showed extensive thickening of the pleura of the entire right chest; the left lung was entirely clear.

The patient at first was placed on 30,000 units of penicillin and 5 grams of sulfadiazine daily. On October 19 this was discontinued, and she was placed on 200,000 units of streptomycin every three hours. On November 15 this was increased to 250,000 units every four hours. From then on there seemed to be progressive improvement. The remaining fluid in the peritoneal cavity cleared completely, she felt stronger and her temperature receded to about normal. On November 26 she began sitting up at the side of the bed. She began noticing vertigo and was given niacin and benedryl. Temperature dropped down to normal and remained so for several weeks before discharge. Pulse ranged between 70 and 100. Dr. Wesley Spink of the University was called in consultation, and he corroborated the diagnosis and concurred with the treatment. She left the hospital on December 18, 1946.

Not long after returning home, she noticed that the abdomen had begun to enlarge again and the temperature had begun to rise. She was readmitted to the hospital on February 15, 1947, with a temperature of 101.6°. She was now given 375,000 units of streptomycin every three hours. This was later changed to 500,000 units every four hours. She promptly began to improve, and the fluid slowly disappeared from the peritoneal cavity without aspiration. The temperature also started to decline. After March 8 it did not exceed 99°. After April 13 for several days it again reached about 100°, but after May it did not rise above 99.6°. Her pulse was 90 to 110, and general condition was excellent. The patient was discharged May 16. This time on discharge the vertigo was quite pronounced. She would sway from side to side in walking and would have to hold on to something. Gradually this left her, but she is still somewhat dizzy and at times a little uncertain in her gait. There has been no recurrence of the peritonitis. The abdomen is soft, not tender, and appears entirely normal. When last seen, December 22, 1947, she seemed to be in good physical condition.

Case 2.—Mr. E. B., aged fifty-seven, was first seen September 25, 1947. He complained of gas and belching of about a year's duration, some dysuria, some alternating constipation and diarrhea for about a year, progressive weakness, pain and tenderness in the abdomen, and swelling of both legs.

Physical examination showed him to be 5 feet, 7½ inches tall, weighing 133 pounds. Blood pressure was 114/70; the heart seemed normal, with tones of good quality, the abdomen was somewhat distended, tympanitic and tender throughout, especially at the right lower quadrant. A small tender mass in the region of the cecum was felt. The tenderness had been increasing the previous six weeks. The right testicle was atrophied and there was edema of both legs from the knees down. The urine was negative. Hemoglo-

Fig. 1 (Case 2). Photomicrograph of a section of peritoneum. The endothelial surface is above. Note the closely approximated tubercles containing large giant cells.

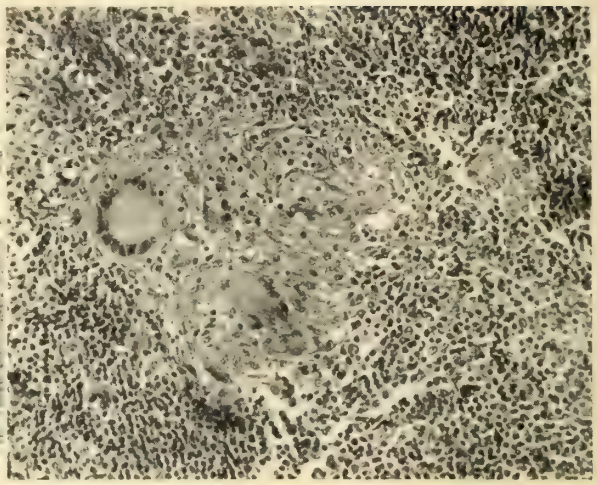

Fig. 2 (Case 2). A tubercle in a lymph node shows a nest of epithelioid cells and two giant cells.

bin was 75 per cent, white blood cells 7,200. An x-ray of the chest showed the heart not enlarged; the lungs showed a hard, dense shadow at the right apex mesially. The x-ray diagnosis was an arrested fibrous tuberculosis of the right upper lobe. The electrocardiogram was negative. Because of the abdominal discomfort, gastrointestinal x-ray studies were ordered. These were reported as showing extensive massive carcinoma involving the proximal half of the stomach. X-ray of the colon also showed a definite deformity of the cecum, rather extensive, with changes extending into the terminal ileum. This suggested a diagnosis of tuberculosis of the cecum and terminal ileum.

The patient was admitted to the Asbury Hospital on October 6, 1947. He was given several transfusions preparatory to operation. A laparotomy was done by Dr. Maxeiner on October 20. The findings were very surprising as well as striking. The entire peritoneum, both visceral and parietal, was studded with myriads of tubercles 1 to 2 millimeters in diameter. The stomach, omentum and mesentery were completely covered with tubercles, but there was no evidence of a neoplasm in the stomach. The cecum showed an indurated mass, probably inflammatory. Small pieces of tissue from the peritoneum and several lymph nodes were removed for microscopic study. Microscopically they showed an active type of miliary tuberculosis with areas of necrosis and large giant cells (Figs. 1 and 2). Temperature on admission was 100°, which rose to 102° and then fluctuated, reaching 103.6 following the operation. On October 26 streptomycin was started, 400,000 units intramuscularly every eight hours. On November 7 his weight was 113 and on November 29 it was 123 pounds. His blood showed 77 per cent hemoglobin, 7,800 white blood cells.

He improved very rapidly, so that a re-ray of the stomach, December 15, showed an absence of the deformity which had been diagnosed carcinoma in the previous gastrointestinal study. The cecum still showed deformity. He started getting up and around, was gaining in weight and in strength, and he left the hospital, December 24, feeling quite well. The tenderness of the abdomen had completely disappeared, and the mass at the cecum had also cleared. Pulse was 66, blood pressure normal. When last seen on February 11, 1948, he was feeling entirely well, had no complaints, was up and around and had a very good appetite. The abdomen appeared entirely normal.

Discussion

These two patients present a complete change of prognosis in cases of advanced tuberculous peritonitis. The disease in both cases has been definitely arrested. As to whether this will remain permanent or not, only the future will tell. However, the discovery of streptomycin has definitely altered the outlook and the course in a large variety of infections, including those caused by Gram-negative bacteria, but especially in certain types of tuberculosis. The literature presents an increasing number of articles dealing with the excellent results obtained in the use of streptomycin in tuberculosis as well as in other infectious diseases.

Discussion

Dr. William B. Tucker: This is very much the tail that is *not* going to wag the dog. Dr. Barron has so far very well covered the whole problem of the treatment of various tuberculous conditions with streptomycin. All that streptomycin has done for us is to *aid* in curing tuberculosis. The action of the drug is suppressive at best, and it still remains for resistance of the body to overcome the disease. The probable mechanism of action of streptomycin on tubercle bacilli is related to the problem of bacterial resistance. Apparently streptomycin is bacteriostatic. Tubercle bacilli divide by fission and increase in size, and only when they have attained a certain size do they appear to be capable of reproduction. The action of streptomycin seems to be suppression of growth and reproduction, not killing. It has now been established that not all tubercle bacilli are suppressed by streptomycin. Probably all populations of tubercle bacilli initially contain a small percentage of bacilli which are resistant to streptomycin, but the action of streptomycin is greater on the vast majority of tubercle bacilli in the population which are sensitive, and gradually over a period of time those that are not resistant are suppressed, but the others keep on growing and reproducing. Finally the initial percentage is reversed, a few may still be sensitive, but the vastly higher percentage is resistant.

As in all chemotherapy, one has to take into account the ratio between therapeutic dosage and that causing toxicity. Where the range between the two is high we have little difficulty. Such is not the case with strep-

TABLE I. DEVELOPMENT OF RESISTANCE TO STREPTOMYCIN

Percentage of organisms resistant to 10 mcgm./c.c. or more.

	2gm./day	1 gm./day
After 60 days treatment	35	33
After 90 days treatment	70	74
After 120 days treatment	83	96

TABLE II. INCIDENCE OF TOXICITY

Percentage of patients manifesting toxic reactions.

	2 gms./day in 5 doses	1 gm./day in 2 doses
Vertigo	92	17
Diminished caloric stimulation	77	12
Eosinophilia (over 4%)	70	22
Renal irritation	67	16
Impairment, renal function	1	0
Gastrointestinal disturbances	10	6
Paresthesia	3	4
Deafness	1	0
Fever	8	5
Dermatitis (mild)	18	0
Leukopenia	2	0
Treatment stopped or interrupted because of toxicity	8	3

This last statement is demonstrated from the figures given in Table I.

Allowing for the size of samples, there is no significant difference in the rate of development of resistance to streptomycin on the two dosage regimens.

The point made earlier, as to the reduction in the incidence of toxic manifestations on the smaller daily doses, is illustrated in Table II.

There can be no question as to the significance of the reduction of incidence of toxic reactions on the 1 gm./day as compared with the 2 gm./day regimen. It is entirely probable that as still smaller doses are explored, still further reductions in toxicity will be made possible.

Enough experience has now been accumulated to know in what tuberculous conditions streptomycin is most effective, moderately effective, or least effective. The experience at the Minneapolis Veterans Administration Hospital is best summarized in Table III.

The conditions have been listed in approximately the rank of the decreasing effect of streptomycin with respect to improvement of the condition.

That these results are not atypical, Table IV is presented to indicate how closely the results here correspond to the over-all experience of the other Veterans Administration Streptomycin Study Units.

TABLE III. RESULTS OF STREPTOMYCIN THERAPY ON TUBERCULOSIS IN THE MINNEAPOLIS VA HOSPITAL

Treatment-completed cases only

	Healed	Improved	Unchanged	Worse	Total	Died
1. Glandular	4	1			5	
2. Alimentary Tract	2	2			4	
3. Sinuses-Fistulas	4	2	1		7	1
4. Laryngeal	3	5	2		10	1
5. Tracheobronchial		5	1		6	
6. Skin-Pericardial		2			2	
7. Genito-urinary	1	4	4	1	10	
8. Empyema		1	1		2	1
9. Pulmonary		10	2	7	19	6
10. Bone and Joint		1		1	2	
11. Miliary-Meningeal	1	1		3	5	3
Totals	15	34	11	12	72	12

tomycin. One great difficulty in the use of streptomycin has been to find a therapeutically effective dose which will avoid the complications of toxicity.

The Veterans Administration has twenty-one hospitals throughout the country which have been co-operating with the army and the navy, and these hospitals have had an unparalleled opportunity for making a study of these problems. The Minneapolis Veterans Administration Hospital began its share in the study just a year ago yesterday when we treated our first patient. The Veterans Administration Streptomycin Study Program as a whole has treated over 1,000 patients and we have learned the following, very briefly:

1. It is not necessary to treat with as high doses as originally thought, as Dr. Barron has indicated. We are in the process of studying even smaller doses, and maybe 0.5 gram, or even 0.2 gram a day, is as effective as 1 gram.

2. We have also learned that it is not necessary to give numerous injections every day. We are now using two doses a day, but there may be no reason why we should not give it every other day or once a week. The probable explanation for this is related to the life cycle of the tubercle bacilli.

3. Another point clarified has been the relation of toxicity to dosage. On 1 gram a day the toxic manifestations of earlier larger doses have been largely eliminated.

4. We still have not avoided the other horn of the dilemma—the development of resistance to streptomycin on the part of some tubercle bacilli. The rate of development of bacterial resistance is probably as rapid with smaller as with larger doses.

TABLE IV. APPROXIMATE RANK OF EFFECTIVENESS OF STREPTOMYCIN IN VARIOUS TUBERCULOUS CONDITIONS

Type of Tuberculosis	20 V.A. Study Units	Minneapolis
Group A: Effective (85%-90% Improvement)		
Sinuses and Fistulae	1	3
Alimentary Tract (Mouth, Intestinal, etc.)	2	2
Laryngeal	3	4
Tracheobronchial	4	5
Glandular	5	1
Group B: Moderately Effective (60%-80% Impr.)		
Genito-Urinary	6	7
"Rare Medical" (Skin, Serous, Iritis, etc.)	7	6
Empyema	8	8
Pulmonary	9	9
Group C: Limitedly Effective (30%-45% Impr.)		
Bone and Joint	10	10
Miliary and Meningeal	11	11

In summary, then, we have learned a great deal about the relative degrees of effectiveness of streptomycin in various tuberculous conditions, and have found 1 gm./day an effective dose, and one which appreciably reduces the incidence of various toxic manifestations. There still remains the serious problem of the development of bacterial resistance to streptomycin. The period of most rapid development of resistance may be as early as between forty-five and sixty days. And the development of resistance to streptomycin is probably largely an irreversible phenomenon. It behooves us, in considering streptomycin therapy of a tuberculous condition, therefore, constantly to keep in mind the pos-

sibility of the development of resistance. If it does develop, and is an irreversible phenomenon streptomycin therapy in tuberculosis must be looked upon largely as a gun containing only one shot. We need to hold back and not use streptomycin prematurely or unwisely. We probably have few opportunities (possibly only one in the majority of cases) to use it in the treatment of tuberculosis, and we must keep this fact in mind when contemplating streptomycin therapy.

In closing, may I again express appreciation of the opportunity to hear and to discuss Dr. Barron's excellent presentation, not only of his two cases of tuberculosis peritonitis so well treated, but of his treatment of the problem of streptomycin therapy in tuberculosis, as a whole.

Dr. Russell H. Frost: I am grateful for the opportunity of attending this meeting and of discussing briefly Dr. Barron's most interesting and effective presentation. As a matter of fact, not a great deal in the way of discussion is possible, for the reason that Dr. Barron's own experience in treating two cases of tuberculous peritonitis with streptomycin is probably more extensive than that of most of us here.

Until the advent of streptomycin, the treatment of this condition was far from satisfactory in spite of the fact that many cases—particularly of the so-called serofibrinous type in their earlier stages—did respond slowly to prolonged bed rest and eventually made more or less complete recoveries. In too many others, masses developed which became caseous, sometimes with the formation of abscesses and fistulas or sinuses, and occasionally with the development of intestinal obstruction. Dissemination of the tuberculous process, leading to death, occurred not infrequently.

While it is much too early, of course, to say that streptomycin has solved the problem of the treatment of tuberculous peritonitis—or of any other type of tuberculous disease—there can be no doubt that in the relatively early cases in which marked tissue changes have not yet developed—and I have seen two such cases and know of some eight or nine others—we have in streptomycin a drug which frequently or even usually produces a startling and dramatic improvement in both the patient's local and general condition, sometimes within a few days. No case, to my knowledge, has been followed long enough to be certain that the process has been permanently arrested. As one bit of evidence, I know of two individuals who had peritoneal biopsies both before and after streptomycin therapy, the initial biopsy revealing unquestioned widespread tuberculosis, and the posttreatment biopsy a normal peritoneum, both grossly and microscopically. On the other side of the coin there is the patient with tuberculous peritonitis who developed tuberculous meningitis and who was treated with streptomycin by Hinshaw in 1946, with apparent control of both processes. This patient recently returned to the Minneapolis Veterans Administration Hospital with a large, firm, nontender mass (the size of an orange) in the right side of his abdomen. This was felt to be a tuberculous mass (rolled-up omentum?) by all who saw him. This mass "pointed" and appeared to be about to open and drain spontaneously through the anterior abdominal wall when, gradually and without treatment of any kind, the process reversed itself and the mass disappeared over a six- to eight-week period. In for a check-up last week, the patient had an apparently normal belly and seemed to be perfectly well. Both he and Dr. Barron's cases should be interesting and instructive to follow.

My congratulations to Dr. Barron for his splendid report.

Dr. Ralph Creighton then read his inaugural thesis on "Military Medicine Needs the Medical Profession."

MILITARY MEDICINE NEEDS THE MEDICAL PROFESSION

RALPH CREIGHTON, M.D.

Minneapolis, Minnesota

This may appear to be an odd subject on which to base a thesis for a scientific group; yet it is a medical subject because it deals with medical men and their efforts to render medical service. I believe it is a timely and important subject, particularly now when our world is in a state of jealous ferment. This paper is about doctors, like you and me, who are suddenly transferred to a strange environment, at a time of great emotional strain. Here they are called upon to perform many unusual duties in addition to, or in place of, the familiar one of caring for sick or injured humanity. They are expected to perform these duties in the midst of great confusion, unsatisfactory conditions, many times while in great personal danger, and too many times to the accompaniment of caustic criticism from those who have made military medicine a profession and should know better.

I ask you to consider with me the situations faced by the temporary medical officer of the last war, and, in the light of his experiences, to see that it is important that you, the medical profession, should interest yourselves in the problems he faced. You must see the importance of lending your interest and influence to the end that the temporary medical officers of future wars shall be able to serve more efficiently and shall not be subject to some of the practices that greatly impaired their morale and efficiency in the national emergency just passed. By interesting yourselves in this reasonable criticism of the service, you can help the Surgeon General to develop a finer medical service in the event of a future sudden emergency. This is the time to study these problems and plan for the future. We hope that these plans may never be used, but just for once let us have our plans matured and firm before war is upon us, rather than throw them together hastily after war has struck. Let us gather together the knowledge gained by those who served last time and, with that as a basis, offer certain constructive criticism to the Surgeon General. I believe he would welcome the interested and forceful help of organized medicine. God forbid that we should enter another emergency making the same old mistakes over again; this method is said by some to be the approved army method.

Medical men who served in the last war were so hypercritical of the treatment accorded them in that war that a national committee has been appointed to consider their complaints with a view to improving their status in the event of another war. The American Medical Association sent a comprehensive questionnaire to all doctors who served in the forces. An analysis of this questionnaire has been made by Dr. Frank Dickinson, and the results of his analysis are most illuminating. I shall refer to them later. You have all heard strange tales of the misuse of medical men, of the waste

---

Inaugural thesis.

of their professional skills, of discrimination and lack of promotions. You have heard that the services called for and absorbed far more medical men than they could use. We cannot be too critical of this, for the army was using the long view and, had the war continued, this pool of men would probably have been used.

As a direct result of this critical attitude of men who have served, insufficient numbers of doctors are joining the Medical Reserve Corps. The National Guard of Minnesota has recently been reactivated. They have been authorized to form a complete infantry division, including, of course, a medical battalion, air services, and certain other auxiliary services, among them anti-aircraft artillery. These units are well on their way to completion except for one factor. They have no medical service. At the present time only three or four doctors have taken commissions in these National Guard units. They are badly in need of medical officers of both company and field grade. This is a serious situation for the National Guard. I have tried to interest several younger men, calling attention to the added advantage of pay. None of the younger men are interested; certainly none who have been in service. Why? Certainly not because they are not willing to serve their country in time of emergency. Why are they not willing to help prepare for an emergency that we hope will never arise? Something unpleasant, deeply unpleasant, has soured our doctors on the services. The medical profession must find out what is wrong and why they feel that way. They must show the Surgeon General the reasons why doctors were dissatisfied with the service, and try to bring about certain changes in the army system.

I have been amazed at how little the civilian, including the medical profession, knows about the assignments that may be given to a doctor in the service. Usually they seem to picture him as carrying on his usual daily routine, the only change being a new environment and a uniform, as though he really had only started to do his work at a different hospital where all the patients were soldiers. People have looked at me with doubt and surprise when I have told them that I never served in a hospital, that all my service had been with troops. How could such things happen to a doctor? Did they really have doctors right with the soldiers? Weren't they all back somewhere in a hospital? The answer, of course, is that there were doctors like you and me who lived and served and went through combat with the line units; yes, and many of those doctors died with them. They served with the infantry, the artillery, the airborne forces, the paratroops, and the tanks. They had no hospitals and they did no hospital work, and, perforce, practiced a sort of educated backwoods primitive medicine and surgery. They were largely isolated from other medical men for periods of time. They had no medical books and, owing to the exigencies of the service, rarely got a medical journal. They went on and on in a monotonous oblivion of poor food and water, dirt, danger, and unending hours of caring for badly injured men. As time went on, they realized that the only relief they probably would ever get would be through the laws of attrition, and that rotation home or to a back area hospital service was a pleasant mirage —like promotion. They learned that once assigned to duty with a line unit, they would probably stay there for the duration. They did have the advantages of belonging to a unit that had considerable *esprit de corps* and had the pride of being a member of that unit. You may have noticed how proud men were of the shoulder patch they wore, and how they looked down on the man who wore the patch of a less spectacular unit. A doctor who served with the 82nd Airborne, or the 36th Division, was proud of his unit, in spite of all the troubles he had. That was the greatest satisfaction he had—he had been there!

May I quote a few items that I have taken from Dr. Dickinson's analysis of the AMA questionnaire?

1. 38.7 per cent of the medical officers in the army had been in general practice, 27.7 per cent were classified as specialists (17.6 per cent were board-certified), the remaining 33.6 per cent were interns or residents on induction to the service.

2. 48.7 per cent of the medical officers in the army never attained a rank higher than captain, and 79 per cent never attained a rank higher than major.

3. The average base pay of the temporary medical officers in our army was $2,826 a year.

4. 23.3 per cent of the doctors in the army served with tactical units.

Our civilian medical officer left with his division for a southern training camp, which he found to be in a God forsaken part of the country. It was partially completed and partially equipped—and alternately knee-deep in mud or baking in the dusty heat. He was now a regimental or battalion surgeon with the infantry or artillery. He found himself holding sick call, going on hikes, and living that healthful outdoor life. He taught first aid to his medical detachment, hoping some of them would be bright enough to remember part of it should the need ever arise. For some reason or other, the personnel section of the army would send all the bright boys to the artillery, engineers or infantry, and figure the dubs were good enough for the medical corps. He trained his men in map reading, in orienting themselves at night, in caring for themselves and their equipment, and how to care for and evacuate wounded under any and all conditions. He went on endless maneuvers. He inspected an endless number of latrines, mess halls, quarters, feet and genitals. To his surprise, he also discovered that the line officers with whom he was in daily contact did not think he or his medical detachment were of any great importance—a nuisance, rather. Later they would change their minds—but no one knew that yet! He also would receive unexpected calls from the regular army medical officers, who would inspect him, his detachment, and his knowledge of things military. Few of them ever seemed to want to help him with his new job, rather, they would make caustic complaints about his ignorance of the army and hope that some time these new officers would learn how to do things right. Never an effort on their part to sit down with a fellow doctor and say, "Here I am, a regular, and know

how to do these things; and I have come over to show you how so we will have a better medical corps." No, never that! These occasional visits became nightmares at times. Suddenly came the news of Pearl Harbor, and a few weeks later our doctor was on the way overseas, still struggling to become an army officer and to do his job the way the army seemed to want it done.

The commanding officer of a line organization is solely responsible for everything that his unit needs or does. He and not the medical officer is responsible for the health of the command. There are sound tactical and administrative reasons for this apparent anomaly. The well-trained line officer will usually let his medical officer run his own show without interference, but there are exceptions in line officers in this respect. The medical officer has certain prescribed duties detailed in army regulations. In addition, he is expected to advise his commanding officer in matters pertaining to the health of the command. This advice may be accepted in part or in total, or may be ignored, for the commanding officer is the party responsible for the results. He may, of course, be condemned by higher authority for not following the advice of his medical officer. So, a medical officer may make an inspection and find many things wrong which may affect the health of the command, but without the backing of his commanding officer, he lacks power of command to force delinquents to comply with regulations. The commanding officer may be intelligent, co-operative, and deeply interested in the health of his command—and most of them were. On the other hand, he may be stubborn, stiff-necked and hard-boiled, glorying in making things tough for himself and his men, he may even be a Christian Scientist or other cultist. I have heard some of these men deny the possible existence of psychosomatic conditions, deny that men may crack up under long days of combat, fatigue, and poor food. He doesn't think battle fatigue exists. He classifies all such cases as "yellow bellies," and wants them all tried by court martial. Even the most patient medical officer of any level—from regiment up to corps or army—may want to throw in his hand if he has a C. O. of this type.

I do not want to give the impression that all line officers were un-co-operative with medical officers. Most of them were grand chaps who thought their surgeon was the best ever and were completely with him in all he tried to do. I do feel, however, they could have been given a better understanding of the importance of a medical opinion. After all, a doctor is a pretty well educated man and smart enough not to underestimate the importance of the tactical situation or the theory of chain of command. I still believe the West Point graduate was the worst offender. Most of the reserve officers and Guard officers had had a family doctor back home whom they always had considered as being a pretty smart man, an important man in their community, a man whose opinion was worth considering. The West Pointer is well trained, pleasant, affable usually, and knows all there is to know about everything. He has a rather cavalier attitude towards the medical man, treats him like a harmless and rather simple child who could not possibly understand the profound thoughts of a military mind. I believe this attitude starts on the highest levels in the war department and is practiced on the Surgeon General just as much as a regimental or battalion commander may practice it on his surgeon.

Getting a replacement medical officer for duty with a combat unit was a major operation, and here was where we began to see where medical personnel were wasted. There were always plenty of medical officers in the replacement depots of the base sections doing nonmedical duties and anxious for a permanent assignment to duty, even as a medical officer in a combat outfit. By some quirk of army administration, it was very hard to pry these men out of the base section replacement depots. When at last they came to us, they told us strange stories of misuse of medical officers. They told us of large numbers of medical officers who remained in the replacement depots of the base sections in North Africa and the Peninsular Base Section in Italy, who were unassigned. They were doing military police duty. They were roaming the streets of Naples, checking to see whether combat troops sent back to the rest areas were wearing their dog tags, or watching to see that they saluted base section officers with the proper snap. They were even learning how to take down and re-assemble a machine gun while blindfolded. Their time was occupied by these and other WPA projects. Base section commanders liked to carry a large roster and were loath to part with these men even if they couldn't put them to proper use. The answer? Once again, a personnel policy in the Surgeon General's department that would see that proper use was made of medical personnel. The medical profession, with its organization, could help correct this abuse.

Military training is a wide gap that the newly inducted medical officer must face. If he were properly briefed by the service on entrance, he would realize its importance to him and to the men with whom he must serve. Proper and adequate orientation on the objectives of training would have produced far-reaching beneficial results. I feel that the regular army fell down badly on this opportunity. Let's make sure that opportunity is not missed next time. Military training should be the process by which a civilian doctor is transformed into an officer of the Army of the United States; a medical officer, it is true, but still an officer with certain duties and responsibilities by virtue of that fact. A doctor cannot enter the army and remain just a doctor; by reason of his rank he must assume another status as well. This transition from civilian doctor to army officer is hard for many to take and causes much unhappiness and misunderstanding. There are many who refuse to accept the officer responsibility but who are willing to accept officer privilege; in fact, they are very jealous of it. Of all the professions, the doctor is perhaps the greatest individualist. It is difficult to convert him to regimentation; and regimentation is very necessary in a military organization. This hostility toward accepting officer responsibility on the part of temporary medical officers was the source of much impatience and criticism from the officers of the regular army. They failed to understand that a newcomer couldn't grasp, on a minute's notice, certain obligations

in which they had had a lifetime of training. Their failure to understand this situation gave them, the regulars, a feeling of frustration and they tended to take it out on the newcomers. As a result, many of them offered training the hard way. A proper orientation course by the regular army, on induction, offered with patience and understanding, would have been gratefully received by these neophytes. All they wanted to know, to start with, was what was expected of them. Do you remember how you felt the first time you appeared on the ward as a very junior intern?

Many of these freshmen medical officers bitterly objected to field training under simulated battle conditions. "What a silly thing to make doctors go through," said they. Later they had cause to wish they had given more effort to learning field duties. There were some unregenerates who never would conform. They should have been reclassified then, for their own good and for the good of enlisted men who later had to serve with them, for many of these enlisted men were contaminated with the same ideas of nonconformism. For the most part, the new medical officer was an earnest soul, an eager beaver, anxious to do a good job if only some one who knew would tell him what that job consisted of in all its parts, and in terms he was familiar with. Like a true scientist, he wanted to know "why" the army did things the way they did, and not just accept them without question. This attitude the regular army instructors did not try to understand. As to why the army did some of the things the way they did, as yet there has been no answer.

I would further offer a criticism of the regular army in the type of training offered and in its selection of officers to conduct that training. In the event of another national emergency, they will do well to select teachers who are not so removed from the professional plane, who have understanding and a true willingness to help convert the doctor into an army officer. We saw too much of the impatient, supercilious, hypercritical type. At times I had the feeling that the regular army officer viewed the new temporary officer through the warped screen of a subconscious inferiority complex. He saw the well-trained, successful medical practitioner that he might have been had he not entered the army. As a result, I believe some of them took their resentment out in making the inexperienced officer ridiculous. This pose affected by many of the regular service was most bitterly resented, and it was a common practice not only in training but afterwards. It was after a session with one of these martinets that we would wonder: why hasn't the medical profession let its interest and well-wishes follow us into service and help control some of these military morons?

It is my contention that all medical officers should have basic field training, regardless of grade and probable future assignment. No one in the service knows what the future may bring in the way of duty. Unless changes are made in the assignment of personnel, no matter how well a doctor is trained, no matter what his age or physical condition, he may wind up with combat troops. Then he has only regrets that he had no field training. This happened to many whose age and professional attainments should have placed them elsewhere. A medic assigned to a combat outfit has a tough time at best, but a much worse time if he is not trained for it.

During the early rough days in Northern Africa, a replacement medical officer reported for duty. His only duty had been in a state-side station hospital, and he had requested overseas duty. He had never had service with troops and had no field training. It was necessary to send him up as a battalion surgeon to an infantry regiment that was heavily engaged. He admitted he had no idea of what his duties would be and no idea of the organization of an infantry medical detachment. He was plunged at once into heavy fighting at a time when the Germans had first started to use their 88's to good advantage. This man took one look at his new assignment, crawled into a foxhole and stayed there for the next forty-eight hours. He was relieved of duty, charged with misbehavior in the face of the enemy, and sent back in disgrace. Was he really a coward, or was he the victim of lack of training and experience? Was he to blame, or was some one else to blame?

The training offered to new medical officers at the Medical Department Field Training School at Carlisle Barracks was at times impractical, inadequate and unrealistic. It was often conducted by men who had little or no practical field experience in the things they taught. Few on the faculty had extensive combat or field background. Many of their graduates had to be completely "untaught" the things they had learned at Carlisle. This was particularly true of field sanitation. We found that modern warfare presented new problems in field sanitation that were not answered in the field manuals, but Carlisle stuck to the field manuals. The teaching of army paper work was uninspired and made drudgery. It *was* drudgery, and could have been simplified for field purposes. This was contemplated, but never quite done. However, no apparent effort was made to explain to these men the importance of the various documents, voluminous and repetitious as they were. As a result, men came overseas with a disrespect for the records they were required to make. On these records depended many statistics of importance, and many records that would, in later years, be the basis for claims against the government.

To touch again on the attitude of the regular army instructor toward the trainees at Carlisle Barracks, this I have heard from the instructors themselves, and I have heard them laugh about it; It was an attitude of "be tough, be arbitrary, make them feel ridiculous, make them 'take it and like it'." Some of them felt it was good technique to haze these trainees for all the world as though they were college freshmen. Now these trainees were doctors like yourselves. Would you have liked it? Would you have resented it? These trainees came to the school to be taught how to do a job by men who presumably knew how. What was still more unfortunate, some of these trainees later aped their instructors, and they themselves became the obnoxious, difficult type of officer you read about later in the newspapers.

The status of the medical officer in relation to the line officer should be overhauled and clarified in the future. I believe this should be done from the Surgeon

General's office right down to the lowest echelon that rates a medical officer. I believe the Surgeon General has had as much trouble putting his ideas across as the battalion surgeon, because of the all-wise line officer or the even wiser supply officer or G-4. It is only a difference of level. Also, the surgeon is generally outranked and has no command function.

Once again let me reiterate, I have no quarrel with the army system of chain of command, nor with the fixing of responsibility on commanding officers of all ranks. These systems are well tried, are practical, and necessary to a unified and smooth working military unit.

I firmly believe that a strengthening of the status of the medical officers of all grades in their relationship to line officers would improve morale and increase the efficiency of the Medical Department. The medic does not enjoy being treated like a step-child. Organized medicine could help considerably in raising the status of the medical officer as an important, intelligent, and trained part of the army. It could help immeasurably by interesting itself in the problems of organization and training faced by the Surgeon General—not by finding fault with his department but by backing him up as an important and honored member of our profession. We should make every effort to include medical officers in our meetings. As a profession, we must take an active interest and actively support the medical service of our armed forces. Rank, pay, and promotion enter the picture, too, in strengthening the status of the medical officer. Considering his attainments, educational background, professional ability and standing in his community, the medical officer is the most underpaid, underranked, and underprivileged officer in the service. He has much to give, but at times has a hard time giving it.

We, as a professional group, can also give aid to the Surgeon General in establishing a satisfactory personnel policy. Our own navy had a better one; so did the British. The army personnel policy, if they ever had one, never seemed to be workable or understandable. It also had a way of being diluted and modified as it passed through successively lower echelons from the Pentagon Building down. Certainly it could be and often was manipulated for personal considerations. There are enough former medical officers in the AMA at the present time who have enough military background and interest to help the Surgeon General in formulating personnel policies that would be fair, workable, and considerate. A policy that would see that duty assignments were made commensurate with age, experience, training and physical condition. The policy could set up a workable arrangement by which medical officers could be rotated within the service, between field service and hospital installations. Men should not be required to serve out the duration in combat units while they gradually lose their professional skills. The policy should also work out a fair and workable plan for rotation home after a certain length of overseas service. In the last war, many men spent all their time in the states and apparently were quite certain, for some reason or other, that they were not going overseas. On my return home from overseas after nearly three years, I saw many hospitals where most of the staff had not been overseas, nor did they expect to go. They were living comfortably and safely with their families. A good personnel policy would equalize these duty assignments.

I fully and firmly believe that the Surgeon General's office would welcome the interested co-operation of the medical profession on these problems if properly approached. We are not trying merely to be critical or vindictive, but want to help build a forward-looking plan that will eliminate some of the ills of the past which undermined efficiency. We want to do this through organized medicine as a gesture of help to other members of the group who have a big and difficult job to do. Certainly we must be able to show to the Medical Department that a policy by which officers assigned to combat units were frozen was a poor policy. They stayed with their units and watched attrition slowly creep up on them. They had little opportunity to do much real medicine and practically no surgery, they had not the equipment to do much of either. Yet, on the skill, judgment, and devotion of these men of low rank, depended the crucial initial treatment and initial triage of casualties. They patched up the terribly wounded, treated their shock, and decided who could and who could not be moved. The satisfaction of follow-up care and definite treatment was denied them. All the time they knew that youngsters out of accelerated courses, with accelerated graduate training, were being given the coveted hospital duties—and promotions.

The Minnesota Academy of Medicine can materially help in correcting some of the defects in the medical department of the Army of the United States. Its members can interest themselves in the problems of the Surgeon General's office. They can encourage helpful co-operation with that office by the medical profession. The army and its reserve components are looking to the medical profession for medical officers; we can help those officers.

It is my considered opinion that certain features of the Medical Department need particular study and correction.

1. A personnel policy that applies equally to all without any flavor of favoritism or influence from subordinate echelons. A policy that will assure:

(a) Reasonable duty assignments, taking into consideration age, physical condition, experience, professional training and military training. Assignments made by a competent medical group.

(b) Rotation of medical officers from field to hospital duties. Also a policy of rotation after reasonable overseas duty to duty in the zone of the interior.

(c) Assurance that nonmedical duties be cut to a minimum. In this regard, however, I would concede that command duty, staff duty, and a reasonable amount of administrative duty are necessary and must be expected.

2. A proper indoctrination program whereby new medical officers are patiently oriented in what the army may reasonably expect of them. In the event of a national emergency, this could well be handled by a team of regular army officers and medical officers with

"...pressure of the gravid uterus mechanically interferes..."

in pregnancy

"Constipation is the rule. The pressure of the gravid uterus mechanically interferes with the function of the small intestine and colon per se and also renders the act of defecation less efficient by its effect on the diaphragm, abdominal muscles and levator ani."

—Bockus, H. L.: Gastro-Enterology, Philadelphia, W. B. Saunders Company, 1946, vol. 3, p. 999.

"Smoothage" for Management of Constipation in Pregnancy

Management of bowel evacuation without the use of irritant laxatives is accomplished with the gentle, nonirritating action of Metamucil—"smoothage."

By providing soft, plastic, water-retaining bulk, Metamucil promotes normal, easy peristaltic movement—the desired action in pregnancy.

Metamucil is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent.

previous army experience but who come from civilian status.

3. More consideration to the training offered new officers and to the men picked to give the training. I believe the professional training is well handled. More training is needed in military medicine and surgery. More basic training, service school training, tactical, administration, and army procedure training is desirable. Above all, this instruction should be given by better instructors—ones who have had actual experience.

4. Less waste of medical personnel. The next war will require more medical services on the home front, for the war will be brought to the civilians. It will be total war. Overstaffing must be carefully watched.

5. Some reorganization of field medical units so that they are in more fluid state and their components may be quickly shifted where needed.

6. A study of the system of promotion. Consideration of higher rank for medical officers commensurate with the duties required of them and the rank of other officers with whom they serve.

7. A consideration of the relationships between the medical officer and the line officer. Better co-operation would be possible if the line officers' attitude were improved.

Those of us who have served are proud of it and have no regrets. There is much that is fine in the service. Most of its plans and methods are sound and well thought out. Most of its personnel are the kind of people we liked. However, it was not as good as it might and should be. We want it to become better and we want to help in that improvement program. We ask you, as part of organized medicine, to lend this improvement program your interest and support to the end that the sick and wounded of another war may have the best possible chance to be brought back to health.

Discussion

DR. HAROLD DIEHL: Dr. Creighton's discussion is very opportune. We have just finished a World War which we would all like to forget, but the world situation obviously makes it impossible to do that. Certainly the analysis Dr. Creighton has made of the status of the medical officer of the army is thoughtful and constructive. Dr. McCarthy and others here could give similar discussions on the basis of their experiences in the navy. Certainly too, Dr. Creighton has an exceptional background for the discussion he has given. He and I served in Base Hospital 26 in France during World War I, and during World War II he served for five years as a medical officer with combat units.

After the end of the recent war, the AMA authorized the establishment of a committee to study the experiences of medical officers and the utilization of medical personnel during World War II. I happened to be a member of that committee. It was that committee that formulated and arranged for the distribution and analysis of the questionnaire by Dr. Dickenson. In these studies we had the closest co-operation of the Surgeons General of the army and navy. A report was made to the House of Delegates of the AMA at its meeting in Atlantic City last June. The first recommendation of this committee was that the Surgeons General of the army and navy be given rank and authority commensurate with their responsibilities. Dr. Creighton is correct; the office of the Surgeon General had no control of the personnel in the various theaters to which Dr. Creighton refers.

In the army organization the Surgeon General was responsible not to the general staff but to General Sommerville of the Service of Supply. In the navy the Surgeon General was more closely related to the high command. In our judgment the Medical Departments of the armed forces should be advisory to the highest echelons in planning military activities and service. There has been some change made in the organization of the army, and the status of the Surgeon General has been improved over to what it was in the last war.

I am convinced that the Surgeons General of the army and navy are just as interested as are you and I in getting the finest officers in the army and navy and in offering the sort of service that will attract the highest type of men. Dr. Creighton mentioned that if there is another war the casualties among the military personnel will be small in relation to those among the civilian population. Our country has been fortunate in that our cities have not been touched in either World War I or World War II. What happened to Germany and Japan is evidence of what modern warfare can do to the civilian population. Goering and Hitler made no preparation for the care of civilians. Under strategic bombing, medical services broke down completely and there was terrific and unnecessary loss of life. If there is another war, we can expect that same thing in our own country. In another war it would be catastrophic to have one-third of the medical men taken into the armed forces. They just cannot withdraw such large numbers of doctors from the civilian population.

Plans must be made as to what to do if these possibilities become realities. It is difficult in peacetime to take these things seriously and do the sort of planning that is absolutely essential if we are to survive in a third World War. The AMA at Atlantic City authorized the establishment of a permanent and continuing Council of the AMA on National Emergency Medical Service. I was appointed a member of that Council. It is studying these things which Dr. Creighton has mentioned. One thing that concerns all of us is the time, effort and thought that needs to be given to it and the important part that medical societies will have to play to get these things done. Discussions such as Dr. Creighton's are helpful in pointing out the job that the medical profession has to do.

The meeting was adjourned.

AERO MEDICAL ASSOCIATION MEETS

Aviation medical experts and scientists from many parts of the world gathered in Toronto, Canada, June 16, 17, and 18 for the first meeting of the Aero Medical Association convention in Canada. Under the leadership of Dr. J. W. Tice of Hamilton, president of the association, aero-medical men discussed the latest developments in aviation medicine, in an effort to make flying safer and more comfortable.

Topics discussed at the convention were: visual standards, decompression sickness, air sickness, aircrew selection, sonics and vibration, night vision, the human factor in aircraft design, physical examination for private flying, survival, color vision, hearing standards, acceleration, personal equipment, anoxia and oxygen equipment.

Representatives were present from Mexico, Brazil, Chile, Norway, Sweden, South Africa, Australia, Holland, France, the United States and Canada.

DOCTORS LIKE THINGS THEY CAN COUNT ON!

Whether it's medicine, instruments, or professional literature the up-and-coming doctor wants ***quality.*** Without assurance of quality the professional reputation of the physician is at stake, so in giving the best of his professional skill he expects the best of those agencies and materials assisting him with his work.

For many years the physicians of Minnesota have learned to rely upon the unquestioned quality of their professional publication: Minnesota Medicine. Its scientific articles are of the best, and its advertising policy of granting space only to those products which are A.M.A. Council-accepted gives Minnesota physicians the assurance that they can rely upon what is published in their official publication.

Those advertisers who help bear the cost of publishing Minnesota Medicine gauge the value of their advertising by "reader response." A penny postal from you, requesting free samples or literature, will assist us to retain the patronage of concerns which offer the type of quality products we feel free to recommend to you, as a reader.

In Memoriam

DONALD GREY COLP

Dr. Donald G. Colp of Robbinsdale, Minnesota, died April 14, 1948, at the age of seventy-eight. Taken ill last September in Brazil, he was flown back to the Mayo clinic and was ill several months preceding his death.

Dr. Colp was born at St. Margaret's Bay, Nova Scotia, June 25, 1869. He studied at Carleton College and graduated from the Yale Divinity School in 1897. Later in 1908 he obtained a medical degree from the Minneapolis College of Physicians and Surgeons.

In October, 1900, Dr. Colp married Mabel Adams of Minneapolis. She died in January, 1929.

On July 3, 1931, he married the Countess Utta Larisch-Moennich of Bavaria, whom he had met in Vienna. He is survived by his wife, two sons, Dr. Edward A. and Donald Grey, both of Robbinsdale, and two daughters, Mrs. Robert D. Chellis of Boston and Mrs. Donald G. Burch of Saint Paul.

HARRY WILLARD KLINE

Dr. Harry W. Kline of Anoka, died suddenly March 17, 1948, while celebrating the eightieth birthday of his mother.

Dr. Kline was born November 12, 1894, at Anoka, the son of Dr. and Mrs. James Kline. He graduated from the Hahnemann Medical School of Chicago in 1918 and then joined his father at the Kline Sanatorium in Anoka.

In 1919, Dr. Kline married Lucella Morrison of Saint Paul, who survives him.

HJALMAR ERWIN MORTENSBAK

Dr. H. E. Mortensbak, formerly of Hanska and New Ulm, Minnesota, died April 10, 1948.

He was born in Wood Lake Township, August 19, 1910, and was graduated from the University of Minnesota Medical School in 1935. After serving an internship at the Minneapolis General Hospital he located at Hanska. He practiced at New Ulm from 1944 to 1946, when he moved to Great Falls, Montana.

On June 3, 1939, Dr. Mortensbak married Muriel Swihart of Balaton who, with four children, survive him.

He was a member of the Redwood-Brown County Medical Society, the Minnesota State and American Medical Associations.

RUSSELL R. NOICE

Dr. R. R. Noice of Minneapolis died in Miami, Arizona, on April 15, 1948.

Dr. Noice was a graduate of North High School, Minneapolis, and obtained his medical degree from the University of Minnesota Medical School in 1915.

He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations.

Dr. Noice is survived by his wife, Gladys, a sister Mrs. Marvin Wickham of Minneapolis and a brother, W. C. Noice of Lisbon, North Dakota.

WOMAN'S AUXILIARY

Nicollet-Le Sueur

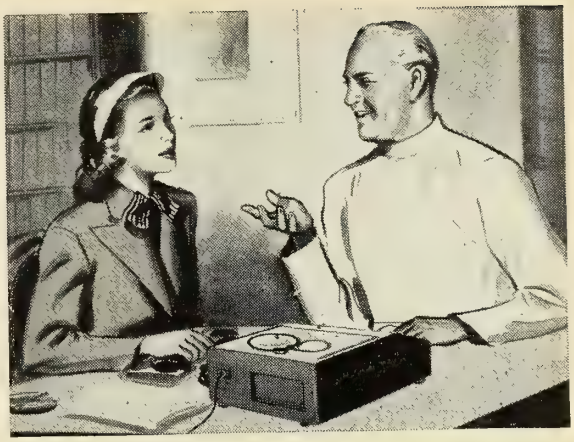
The Auxiliary of the Nicollet-Le Sueur Medical Society held a tea, Wednesday, April 14, at Rundstrom Hall on the Gustavus Adolphus Campus, St. Peter. Dr. Robert N. Barr, of Minneapolis, guest speaker, gave an informative talk on "Cancer." Members as well as the public were invited. At the same meeting high school and college girls were invited to hear a talk given by several county nurses, the college nurse and the public school nurse on the shortage of nurses and the need for recruitment of girls for the nursing profession.

Southwestern Minnesota

At the April 12 meeting of the Southwestern Minnesota County Auxiliary, Dr. Reynold Jensen, assistant professor of Child Psychology of the University of Minnesota, gave a talk.

On April 25, Auxiliary members and doctors met for a joint meeting. Speakers at this meeting were Mr. M. F. Brist, attorney for the State Medical Association; Arthur M. Calvin, executive of the Minnesota Hospital Association, spoke on behalf of the "Blue Cross," and acting as director of Minnesota Medical Service, told of the progress of "Blue Shield," giving a full explanation of the setup of the two groups.

DOLLARS AND CENTS — AND CANCER



The American Cancer Society advances the argument that strictly on a dollars-and-cents basis—the least of the costs of cancer—it is good business to finance research for a cure for the disease.

The ACS points out that the price of cancer to this nation runs as high as $2 billion a year—a staggering sum. This includes estimates of medical fees, hospital charges and even cemetery plots and headstones for those who die before their time. It does not include some important intangibles, however—like the full value of the wage-earner to his family, the damage done a home by the loss of a wife and mother, the future worth of a child to his family, community and nation. The dollars-and-cents yardstick cannot measure the pain of cancer patients, the heartaches of their families and the great concern that all of us feel while cancer is around to menace us. These costs are not borne by a few. For every two homes in America there is one cancer death.

Cancer's toll of two billion dollars a year means a contribution of $14 for every man, woman and child in the United States.

In our efforts to find the cause and cure, the nation has made little more than a token effort. Government financing of research and services has risen only recently from $1.5 to $14 million a year. The American Cancer Society, has spent up to $12 million a year. Total these public expenditures, and the answer is $26 million—an annual expenditure of 18 cents per person for research, clinics, detection centers, public education and services to the cancer sick.

Each of us pays $14 a year in involuntary tribute to cancer; but to eradicate the disease, to end the incidental human suffering and to prevent the premature loss of services of the 188,000 people who die of cancer each year our individual effort amounts to 18 cents.—*ACS News Service*, January, 1948.

Why more Doctors are using

Webster-Chicago

Electronic Memory

The portable, light weight Webster-Chicago *Electronic Memory* Wire Recorder is solving one of today's most difficult problems—helping doctors to increase the effectiveness of their working hours and to see more patients.

It is widely used in consultations to record the patient's case history for comparison and analysis. Significant details are retained for later reference, nothing forgotten. Consultation opinions and running comments made during treatment may be played back as desired... or transcribed later by a stenographer.

Recordings may be kept indefinitely, replayed thousands of times... or erased simply by re-recording on the same wire. Just plug the *Electronic Memory* into an AC outlet and it is ready to record or playback any sound. A sensitive microphone and three spools of pretested *Electronic Memory* Recording Wire are supplied and can be stored in the detachable lid.

Mail the coupon for booklet describing and illustrating America's leading Wire Recorder.

Reports and Announcements

AMERICAN COLLEGE OF SURGEONS

The thirty-fourth clinical congress of the American College of Surgeons will be held in Los Angeles, California, with headquarters at the Biltmore Hotel, from October 18 to 22. The program of scientific sessions will be supplemented by operative clinics in hospitals in Los Angeles and vicinity, by showings of operations by television and motion pictures, and by a four-day hospital standardization conference for hospital personnel. There will also be extensive technical and scientific exhibits.

At the convocation which will be held on the final evening of the meeting, approximately 600 initiates will be received into fellowship. The American College of Surgeons now has a total fellowship of more than 15,000 surgeons, including those not in the United States.

SOCIETY OF AMERICAN BACTERIOLOGISTS

The forty-eighth annual convention of the Society of American Bacteriologists was held in Minneapolis, May 10 through 14, attended by 1,200 scientists from the United States and Canada. Meetings were open to all persons interested in bacteriology.

The society's annual lecture, the Oswald T. Avery Lecture, was delivered on May 13 by Dr. Rene Dubos of the Rockefeller Institute for Medical Research.

AMERICAN CONGRESS OF PHYSICAL MEDICINE

The twenty-sixth annual scientific and clinical session of the American Congress of Physical Medicine will be held September 7 through 11 at the Hotel Statler, Washington, D. C. All sessions will be open to members of the medical profession in good standing with AMA.

In addition to scientific sessions, instruction courses will be offered in two groups. One set of ten lectures will be based primarily on physics and physiology, and attendance will be limited to physicians. The other set of ten lectures will be more general in character and will be open to all physicians and to physical therapists who are registered with the American Registry of Physical Therapy Technicians. Full information may be obtained from the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois.

CHICAGO OPHTHALMOLOGICAL SOCIETY

The Chicago Ophthalmological Society announces that its second annual clinical conference will be held November 29 to December 4. Special attention will be paid to the pathologic and clinical aspects of glaucoma and retinal diseases. Recent advances in general ophthalmic therapeutics also will be presented. The class will be limited to fifty. Further information may be

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The Minnesota Society of Neurology and Psychiatry met in St. Mary's Hospital in Rochester on May 29. The one-day session began with surgical clinics held by the neurosurgical staff in the operating rooms of the hospital. During the remainder of the morning, papers were presented by Dr. K. B. Corbin and Dr. F. J. Millen, Dr. A. R. MacLean and Dr. R. G. Bickford, Dr. J. G. Love, and Dr. H. P. Rome, all of Rochester. Following a luncheon in the Mayo Foundation House, an address entitled "The Art of the Lapidary" was presented by Glen M. Waters.

RED RIVER VALLEY ASSOCIATION

Twenty-five physicians, many of them accompanied by their wives, attended a dinner meeting of the Red River Valley Medical Association in Crookston on April 30. Following the dinner a motion picture on child behavior problems was shown and discussed.

Principal speaker of the evening was Dr. C. O. Erickson, Minneapolis, who spoke on electroshock therapy in psychiatric disorders. Plans were made to hold the next meeting of the organization on July 23 in Thief River Falls.

WASHINGTON COUNTY SOCIETY

The Washington County Medical Society held a previously postponed meeting at Forest Lake on May 11. Only three members were absent. The meeting was devoted to a presentation of the Minnesota Medical Service plan by Mr. Beise and Mr. Calvin.

The immunization project in the county schools was reported to have been completed on April 9.

STEARNS-BENTON COUNTY SOCIETY

Principal speaker at the regular monthly dinner meeting of the Stearns-Benton County Medical Society in St. Cloud on May 20 was Dr. Charles Rea, Saint Paul. Dr. Rea, an instructor in surgery at the University of Minnesota Medical School, spoke on "Intestinal Obstruction." Forty-five members of the society attended the meeting.

SOUTHWESTERN MINNESOTA SOCIETY

At the final meeting of the season, held in Worthington on May 24, members of the Southwestern Minnesota Medical Society heard a talk on "Endocrine Gland Preparations" by Dr. C. J. Ehrenberg, Minneapolis. An obstetrician, Dr. Ehrenberg is an associate clinical professor at the University of Minnesota Medical School.

Also on the program at the meeting was Dr. R. F. Pearson, Slayton, who reported on eight cases of trichinosis recently developing from one source of infection in his community.

SAFE SUPPORT for this HERNIAL PATIENT

Welcome ! SPENCER EXHIBIT 95th Annual Minn. Med. Assoc. Conv. BOOTH 63

The Spencer Abdominal Support for this hernial patient was *individually designed, cut, and made* at our New Haven plant—after a description of the patient's body and posture had been recorded and detailed measurements taken.

The pull of supporting the abdomen is placed on the pelvis, not on the spine at or above the lumbar region. Abdominal support is from below, upward and backward, paralleling the natural pull of muscles. Made of non-elastic materials, the support will not yield or slip under strain, assuring maximum *safety*.

Following application of her Spencer Support, the patient obtained relief of symptoms and was able to return to her job.

Spencer Supports for men, women, and children are each individually designed for each patient.

For a dealer in Spencer Supports look in telephone book for "Spencer corsetiere" or "Spencer Support Shop," or write direct to us.

It was announced on April 21 that Dr. H. R. Ransom, who had been practicing medicine in Osseo since leaving Crosby about two years previously, planned to return to Crosby to become associated in practice with Dr. James B. Nixon in the Cuyuna Range Clinic.

* * *

"The Role of Antihistaminic Drugs in the Treatment of Allergy" was the title of a paper presented by Dr. William S. Eisenstadt, Minneapolis, at the thirty-seventh semi-annual postgraduate extension course of the Lyon-Lincoln County Medical Society in Marshall on April 20.

* * *

A series of lectures were presented by Dr. W. B. Martin, Rochester, at a course in physical medicine at the Veterans Administration Hospital at Hines, Illinois, on May 3 and 4. Subjects for the lecture series were "Prescription Writing in Physical Medicine" and "Microwave Diathermy."

* * *

It was a triple celebration on April 30 for Dr. F. W. Mayer, Sr., of Saint Paul. The three events which were celebrated were his birthday, the forty-fifth anniversary of his graduation from the University of Maryland Medical School, and the completion of his thirty-ninth year in the practice of medicine in Saint Paul.

In Rochester, at the annual health day meeting of the Four-Counties Medical Society Auxiliary and the Altruistic Club, on April 21, Dr. Howard P. Rome, consultant in psychiatry at the Mayo Clinic, spoke on "Psychosomatic Medicine" and presented motion pictures to illustrate his lecture.

* * *

A spring chest clinic was held in Faribault on May 3 by Dr. Karl H. Pfuetze, superintendent of Mineral Springs Sanatorium. Dr. Pfuetze administered the Mantoux test to persons desiring it and also examined ex-patients of the sanatorium living in the area. On May 4 he conducted a similar chest clinic in Morristown.

* * *

More than 700 persons from Elbow Lake and the surrounding area paid tribute on April 18 to Dr. E. T. Reeve in an "appreciation celebration." Dr. Reeve has practiced in Elbow Lake and Grant County for forty-eight years, during which time he has delivered more than 2,000 babies.

* * *

Dr. Ralph T. Knight and Dr. Joe W. Baird, Minneapolis, announce the association of Dr. Stanley P. Wesolowski, Dr. Frederick H. Van Bergen and Dr. Ellis N. Cohen in the practice and teaching of anesthesiology, with headquarters at 412 Delaware Street S.E., Minneapolis.

* * *

Among Minneapolis physicians who attended the recent meeting of the American College of Physicians in San Francisco were Dr. O. L. Nelson, Dr. Wesley Spink, Dr. Cecil J. Watson, Dr. A. C. Kerkhof, Dr. H. O. Altnow, Dr. S. Marx White, Dr. George E. Fahr, Dr. Russell C. Lindgren and Dr. Clyde A. Undine.

* * *

During the month of May, immunization against diphtheria and smallpox was carried out in the schools of Stillwater by the local physicians. This completed the immunization of school children in the county for this year. Chairmen have been named to canvass the county for registration for the chest x-ray survey to be conducted in Stillwater from July 22 to September 30.

* * *

Dr. J. E. Jenson, formerly of Eau Claire, has been associated with Dr. J. W. Stuhr of Stillwater since June 1. A graduate of the University of Minnesota Medical School, Dr. Jenson was on the plastic surgery staff at Valley Forge General Hospital, Phoenixville, Pennsylvania, for two years during World War II. For the past year he practiced at Eau Claire.

* * *

A special meeting of the Southwestern Medical Society and Auxiliary was held on April 26 to discuss the Blue Shield plan. Speakers for the occasion were A. M. Calvin, executive director of the Minnesota Hospital Service Association and acting director of Minnesota Medical Service, Inc., and E. Manley Brist, attorney for the Minnesota State Medical Association.

* * *

One of the speakers at a gathering of Lake Minnetonka residents on May 7 to discuss lake pollution was Dr. W. W. Rieke, Orono township health officer, who

said that lakeside dwellings with outdoor facilities built close to the lake during low water stages now constitute a particular health menace, since earlier lake levels have been restored.

* * *

Dr. Ernest M. Hammes, Jr., has become associated with his father in the practice of psychiatry and neurology with offices at 1124 Lowry Medical Arts Building, Saint Paul. Dr. Hammes, Jr., graduated from the Harvard Medical School in 1941, served in the army for five years, his last assignment being consultant in neurology to the First Army. For the past three years he has been a Fellow in neurology and psychiatry at the Mayo Foundation.

* * *

Dr. Robert A. Aldrich of Anoka, at present a senior resident physician at the University Hospitals in Minneapolis, has been awarded a year's fellowship for graduate study in pediatrics by the National Foundation for Infantile Paralysis. Dr. Aldrich served in the navy after graduating from Northwestern University Medical School in 1944.

* * *

Swanville lost a physician late in March when Dr. John Ylvisaker, who had been associated with Dr. E. J. Simons and Dr. E. G. Knight in Swanville for seven months, left for Minneapolis to practice in an office in the Medical Arts Building during April, May and June. Dr. Ylvisaker planned then to go to a hospital in Detroit, Michigan, to continue his medical practice.

* * *

In April, Dr. Bradley Kusske, son of Dr. A. L. Kusske of New Ulm, became associated in practice with Dr. Howard A. Vogel of New Ulm. A graduate of the University of Minnesota Medical School, Dr. Kusske was in military service for two years, then practiced for six months at Caledonia before joining Dr. Vogel.

* * *

In April it was announced by the Peterson-Lenont Clinic of Virginia that Dr. Robert Petey would soon open an office in Buhl for the practice of medicine. A graduate of Harvard, Dr. Petey interned at Ancker Hospital, Saint Paul, and at the University of Minnesota Hospitals. He served in the army for approximately three years.

* * *

Dr. Carl O. Rice has been elected president of the Minneapolis Surgical Society to succeed Dr. L. Haynes Fowler. Other officers are Dr. Edward A. Regnier, vice president; Dr. Hamlin A. Mattson, recorder; Dr. Rudolph E. Hultkrans, treasurer, and Dr. Ernest R. Anderson, secretary. Dr. W. R. Jones was chosen a member of the Council.

* * *

Announcement was made on April 26 by Dr. B. O. Mork, Jr., Worthington, that Dr. R. W. Robinett, who had been taking postgraduate work at the University of Minnesota Medical School, had joined the staff of the Worthington Clinic. Dr. Robinett, whose specialty is internal medicine, is a graduate of Western Reserve University, Cleveland, Ohio.

Two Rochester physicians were on the program at a meeting of the Park Region District and County Medical Society at Fergus Falls late in April. Dr. D. O. Ferris presented a paper entitled "Treatment of Traumatic Injuries of the Genito-urinary System," while Dr. Roger L. J. Kennedy spoke on "Osseous Changes in Some Disease of Children."

* * *

Speaking at a health panel at the Labor Welfare Institute in Minneapolis on May 8, Dr. Clare Gates, assistant city health commissioner, said that the per capita tax expenditure for health in Minneapolis should be $1.50 instead of the 71 cents it was last year. One of the primary needs of the city, to be filled when additional funds are available, he said, is a maternal and child health program under the direction of the city health department.

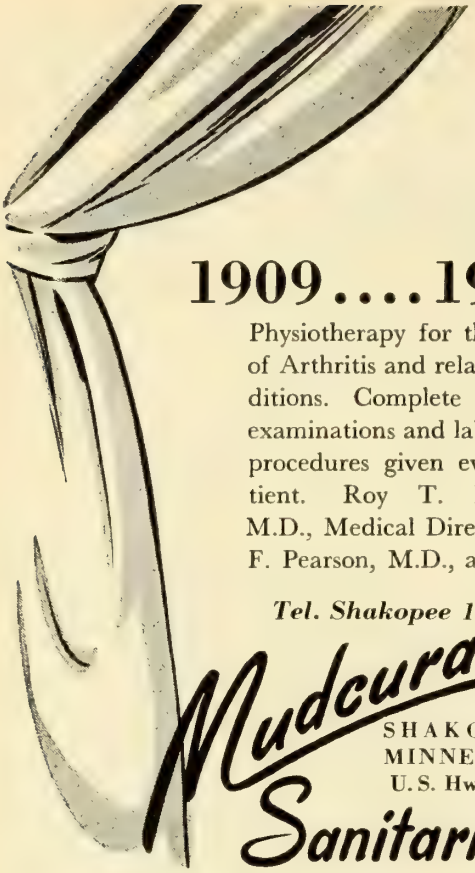
* * *

At a meeting of the Medical Association of the State of Alabama at Mobile during the middle of April, Dr. Andrew B. Rivers, Rochester, gave a motion picture demonstration and presented a talk on "The Syndrome of Peptic Ulcer Perforating into the Pancreas." Later in the month he discussed the same subject at a meeting of the State Medical Association of Texas in Houston.

* * *

At the recent annual meeting of the American Association of Anatomists in Madison, Wisconsin, Dr. A. T. Rasmussen, professor of anatomy at the University of Minnesota, was elected to the position of vice president. University of Minnesota anatomists presented one-sixteenth of all the papers offered at the meeting, which was attended by representatives of ninety medical schools.

* * *



Dr. Jason K. Hartjen, formerly of Detroit, Michigan, has become associated in practice with Dr. D. H. Garlock and Dr. A. V. Garlock of Bemidji. Dr. Hartjen has conducted a surgical practice in Detroit and Grand Rapids, Michigan, at the Cornell Medical Center in New York, and at Tilton General Hospital in Trenton, New Jersey. During April of this year, before he became associated with the Bemidji physicians, he conducted the practice of Dr. D. H. Garlock while the latter was on a vacation.

* * *

On April 3, Dr. Arthur Felion left Two Harbors for Saint Paul to enter private practice with offices in the Lowry Medical Arts Building. Dr. Felion had been on the staff of the Community Health Center Hospital since February, 1947. Upon his departure for Saint Paul, he was replaced in Two Harbors by Dr. W. F. Nuessle, who plans to remain only until July 1 when he will begin a residency at Ancker Hospital in Saint Paul.

* * *

New staff member of the Bratrud Clinic in Thief River Falls is Dr. W. M. Feigal, a graduate of the University of Minnesota Medical School in 1943. After serving his internship at Minneapolis General Hospital, followed by a residency in urology at the same institution, Dr. Feigal spent two years in the army at Oliver

Address: Registrar, 427 S. Honore St., Chicago 12, Ill.

General Hospital in Augusta, Georgia, where he was chief of the urological section. He is serving as urologist with the Thief River Falls clinic.

* * *

The fourth annual John B. Johnston Lecture was delivered at the University of Minnesota on May 19 by Dr. David P. C. Lloyd, neurophysiologist at the Rockefeller Institute for Medical Research. His subject was "Monosynaptic Reflexes and the Myostatic Unit."

The annual John B. Johnston Lecture honors the memory of the former dean of the University's College of Science, Literature and the Arts, a noted neuro-anatomist and educational administrator, who died in 1939.

* * *

Dr. Philip S. Hench of the Mayo Clinic spoke on yellow fever before the International Congresses on Tropical Medicine on the occasion of the Walter Reed Memorial Celebration on May 12 in Washington, D. C. About 2,000 members and delegates assembled to celebrate the forty-eighth anniversary of the discovery by Dr. Walter Reed of the transmission of yellow fever by the mosquito. The gathering was attended by scientists, physicians and public officials from all over the world.

* * *

Alexandria physicians have paid tribute to the memory of the late Dr. Peter E. Kierland by installing two special children's beds in St. Luke's and Our Lady of Mercy Hospitals in that city. The beds, specially equipped for children up to twelve years of age, were purchased by donations from all Alexandria physicians, who wished to set up a memorial in accord with the late doctor's love for children. Dr. Kierland, who practiced medicine in Alexandria for twenty-five years, died in November, 1947.

* * *

It was announced on May 14 that Dr. F. C. Mann, Rochester, had resigned as a Mayo Clinic governor and as director of the Institute of Experimental Medicine. The reason given by Dr. Mann for his resignation was that administrative duties and responsibilities had been seriously interferring with work in his primary interest, research. The clinic board of governors announced that Dr. Mann would continue with his experimental investigations "with the fullest facilities and unhampered by administrative duties."

* * *

Principal speaker at a meeting of the Minnesota Academy of Ophthalmology and Otolaryngology, held in Rochester on May 14, was Dr. Hugo L. Bair of the Mayo Clinic whose topic was "Surgery of the Eye."

Approximately 100 physicians and their wives attended the meeting which was directed by Dr. T. R. Fritsche, New Ulm, president of the organization. Following evening dinner, motion pictures taken in the Canadian Rockies were shown by Dr. Malcolm C. Pfunder, Minneapolis.

* * *

On April 22, Dr. Mario Fischer, Duluth health director, was asked by a city-county committee to proceed with a fact-finding analysis of plans to develop a county-wide health service in St. Louis County. Such a health

service would supplant the many individual health departments now existing throughout the county. In regard to the proposed plan, Dr. Fischer stated that a combined public health unit undoubtedly would save money, improve service and provide service to rural areas not receiving it.

* * *

Purchase of the Gamble Clinic in Albert Lea by Dr. Clayton E. J. Nelson and Dr. E. S. Palmerton was announced on April 26. The medical establishment was purchased from the estate of the late Dr. J. Will and Dr. Paul M. Gamble, both of whom died in 1947.

Dr. Palmerton has been associated with the Gamble Clinic since 1940, except for two and one-half years which he spent in the army. Dr. Nelson joined the clinic staff in 1945 after his release from the army.

The name, Gamble Clinic, will continue to be used by the purchasers.

* * *

A request for a county public health nurse was rejected by Becker County commissioners at a meeting on May 5. The request had been made by the Clay-Becker Medical Society, of which Dr. R. R. Hendrickson of Sand Beach Sanatorium is secretary.

In a letter to the county commissioners Dr. Hendrickson pointed out that a nurse would be needed to help conduct a contemplated x-ray survey and that also there was great need for such a nurse on a permanent basis. Although no statement was made by the commissioners it was believed that the request was rejected as an economy move.

Eden Valley acquired a new physician early in May when Dr. Henry M. Broker, formerly of St. Cloud, opened offices for the practice of medicine. A graduate of the Marquette University School of Medicine, Dr. Broker interned at St. Joseph's Hospital in Milwaukee, Wisconsin. He then entered the navy, serving first at the U. S. Naval Hospital in Bainbridge, Maryland, at the University of Maryland Hospital and at Johns Hopkins Hospital, after which he was appointed to flight surgeon's training at Pensacola, Florida. As a flight surgeon he served in the Caribbean, the Pacific, the Aleutian and Alaskan theaters of operation.

* * *

New medical director of the Arrowhead Health Center, Inc., in Duluth, is Dr. Donald K. Freedman, formerly of White Plains, N. Y., whose appointment to the office was announced on April 17. Dr. Freedman, a graduate of Tufts College Medical School, has taken postgraduate work at the Yale University School of Medicine and at the Columbia University School of Public Health. He was in the U. S. Public Health Service for five years. In 1947, on a Rockefeller Foundation fellowship, he studied prepaid group medical practice plans in all parts of the country. He recently was medical director of a health and welfare plan in New York.

* * *

Tribute was paid to Dr. Robert L. Bowen, Hibbing, at Hospital Day ceremonies in Hibbing General Hospital on May 12.

ST. PAUL — MINNEAPOLIS

Physicians, nurses, civic leaders and hospital staff members assembled on the occasion to praise the work of Dr. Bowen and to unveil a life-sized portrait of him presented to the hospital by a group of friends. The ceremonies were in recognition of the efforts put forth by Dr. Bowen in instigating the construction of the hospital in 1922 and in bringing it under the supervision of the Sisters of St. Benedict in 1942. Principal speaker for the gathering was Dr. Edward Tuohy of Duluth, who directed the unveiling of the portrait.

A graduate of the University of Wisconsin in 1912, Dr. Bowen interned at Augustana Hospital in Chicago, and later became chief surgeon at Colon Hospital in Panama for two years. He then began his practice in Rood Hospital in Hibbing and at the Range Hospital in Buhl.

* * *

Among Minnesota physicians attending a three-day continuation course in cardiovascular diseases at the University of Minnesota, April 15 through 17, were Dr. Bernette G. Nelson, Menahga; Dr. L. A. Smith, Balaton; Dr. Roy T. Pearson, Shakopee; Dr. Richard N. Sather, Mora; Dr. Alfred S. Nelson, Thief River Falls; Dr. Walter Scott Neff, Virginia, and Dr. R. E. Carlson, Stillwater.

The course included discussions on rheumatic heart disease in children, diagnosis and treatment of acute coronary thrombosis, care of the obstetrical patient with heart disease, advances in the use of cardiac drugs, and diagnosis of congenital heart disease.

With the addition of two members, a medical group in Albert Lea incorporated early in May under the name Medical Arts Clinic.

Joining Dr. D. S. Branham, Dr. S. A. Whitson and Dr. J. P. Person, all of Albert Lea, were Dr. Theodore Hansen and Dr. Ruben F. Schmidt. Dr. Hansen, a graduate of the Nebraska College of Medicine, has been associated with Drs. Branham, Whitson and Person since June, 1946, maintaining an office in Alden. Dr. Schmidt, a graduate of the Wisconsin College of Medicine in 1943, interned at St. Luke's Hospital in Duluth. He is taking over the practice vacated in Alden by Dr. Hansen.

* * *

After practicing in Benson for forty-eight years, Dr. Oscar Daignault sold his practice on April 28 to Dr. Richard P. Griffin, who had been sharing his office since September, 1947.

Dr. Daignault, a graduate of Montreal Medical School in Canada, came to Minnesota shortly after graduation and practiced for a short time in Saint Paul, Dayton and Hancock. He began practice in Benson in April, 1900. In addition to the duties of his practice, he has served as city and county health officer and as coroner.

Dr. Griffin, who purchased the practice, graduated from the University of Iowa Medical School in 1944 and interned at Santa Rosa Hospital in San Antonio, Texas. After serving in the navy for a period, he became associated with Dr. C. I. Oliver at Graceville prior to moving to Benson in the fall of 1947.

Forty physicians gathered in St. Cloud on May 6 for the annual medical conference of the Central Minnesota Chapter of the American Academy of General Practice.

During the day scientific sessions were held, followed by a dinner and a business meeting. Principal speaker at the dinner was Dr. Otto A. Lenz, Minneapolis, who discussed the merger of the American College of Physicians and Surgeons with the American Academy of General Practice.

In attendance at the meeting was Dr. Charles E. Donaldson, Foley, state president of the academy. Dr. A. M. Watson, Royalton, is president of the area chapter.

Among physicians presenting talks and demonstrations at the scientific sessions were Dr. Robert Peterson, Dr. H. B. Clark, Dr. E. V. Wetzel, Dr. L. M. Evans, Dr. James E. Murphy, and Dr. James O'Keefe, all of St. Cloud; Dr. William Hall and Dr. S. Raetz, both of Maple Lake; Dr. F. Baumgartner, Albany; Dr. E. J. Schmitz, Holdingford, and Dr. A. J. Lenarz, Long Prairie.

* * *

At the age of eighty-five, Dr. Alvah W. Jones, Red Wing, resigned as city health officer on May 4 after twenty-one years of service, to complete his retirement from the medical field. He plans to devote his future to literary pursuits.

About six years ago, Dr. Jones retired from an active medical practice, concluding duties that began in 1894 when he moved to Red Wing to take over the practice of his uncle, Dr. Philo Jones. Long before 1894, however, he taught and worked in the wilderness of northern Minnesota, serving part of the time as a member of state geological and geographical survey groups. He was the first school teacher at Tower and later taught at the Norwegian Hauge Seminary there. Moving to the East, he enrolled at George Washington University where he received his medical degree. He then practiced for two years in Washington, D. C., before moving to Red Wing on the invitation of his uncle.

During his years in Red Wing, Dr. Jones has served on the board of education for fifteen years, as president of it for three years. He was official physician at the Red Wing State Training School for nearly eight years. His May 4 resignation ended twenty-one years as city health officer.

HOSPITAL NEWS

The board of directors of the new municipal hospital in Granite Falls announced on April 26 that the operating and maintenance staff for the hospital was complete except for three registered nurses. It was hoped that the three nurses could be obtained before the scheduled opening date of the hospital on June 1. Superintendent of the new hospital is Ellen Phillips, formerly of Worthington, who was superintendent of the hospital at Big Fork for eighteen months before entering the nurses' corps in the army where she served for two years.

BLUE SHIELD NEWS

Number of persons covered by Blue Shield as of May 15, 1948	21,145
Number of Blue Shield cases paid on May 15, 1948	140
Total for 1948	352
Amount paid on Blue Shield cases on May 15, 1948	$ 5,187.23
Total for 1948	13,402.66

The following is an article released by the Associated Medical Care Plans which is the National Association of Blue Shield Plans. This article has been sent to all state medical journals to explain Dr. Paul R. Hawley's appointment as chief executive officer of Blue Shield and Blue Cross and also his relationship to each plan. It is felt that this article will debunk the idea that Blue Shield and Blue Cross are going to merge.

Blue Shield and Blue Cross Form Joint Executive Committee

Agreement was reached late in March between Blue Shield and Blue Cross plans, during their 1948 Semi-annual Conference in Los Angeles, on the forming of a Joint Executive Committee.

As chief executive officer for Blue Shield and Blue Cross, Dr. Paul R. Hawley will be solely responsible to the Joint Executive Committee on all matters of mutual concern to both organizations, reporting directly to each organization separately on those matters as in his judgment are of sole concern to either body individually.

"This merging of interests in the mutual employment of an executive officer does not change the status of either organization," said Dr. L. Howard Schriver, president of the Blue Shield national organization. "It means, simply, that both Blue Shield and Blue Cross recognized the advantage to be gained in securing the leadership of an outstanding administrator such as Dr. Hawley has proved himself to be in his handling of previous responsibilities."

The newly created Joint Executive Committee will consist of six members, equally divided between Blue Shield and Blue Cross Commissions.

J. Douglas Colman, chairman of the Blue Cross Commission, will serve as chairman of the joint committee until the annual meetings of Blue Shield and Blue Cross plans in the fall of 1948.

While the present chairman of the Joint Executive Committee is a representative of the Blue Cross Commission, it was agreed that the chairmanship of this committee should alternate semi-annually. A Blue Shield representative will become chairman of the joint committee immediately following the next annual meetings.

Representing the Blue Shield Commission on the Joint Executive Committee are Dr. L. Howard Schriver, Cincinnati, president of Associated Medical Care Plans

5511 Lyndale Ave. So. LO. 0773 Minneapolis, Minn.

(national association of Blue Shield plans); Dr. F. L. Feierabend, Kansas City; and Jay C. Ketchum, Detroit.

Frank E. Smith, director of the Blue Shield organization, and Richard M. Jones, director of Blue Cross, will hereafter be administratively responsible to Dr. Hawley, and through his office to the Blue Shield and Blue Cross commissions respectively.

Blue Shield and Blue Cross staffs now occupy office quarters at separate locations in Chicago. It was agreed in Los Angeles that both staffs should occupy offices at a common location in order that Dr. Hawley's administrative duties might be simplified. Negotiations are under way currently for the securing of new office space which will adequately house both national organizations.

Since Dr. Hawley assumed his position as chief executive officer for Blue Shield and Blue Cross on April 1, he has been filling many speaking engagements with state medical societies, hospital organizations, and civic clubs.

As one of his first official duties, Dr. Hawley represented Blue Shield and Blue Cross on the executive committee of the recent National Health Assembly, held in Washington, D. C., on May 1-4.

The Minnesota Blue Shield would like to take this opportunity to announce that claims are now being paid weekly instead of monthly. Payments are sent to Doctors of Medicine each Friday for the cases that have been completed during the previous week. By doing this the vast majority of cases will be paid in two weeks or less, thus it will be possible in most instances for the physician to show this allowance on the patient's monthly statement.

MINNESOTA DEPARTMENT OF HEALTH

Improvement of conditions in Minnesota's institutions for the mentally ill, and development of more effective techniques for preventing mental illness, were the chief measures urged by psychiatrists who took part in the first Mental Health Institute to be held in Minnesota. This Institute, designed to acquaint lay leaders with aspects of the mental hygiene problem and with the views of physicians regarding methods for its solution, was held June 7-9 on the University Campus, under the joint auspicies of the State Department of Health, the

UNITED PROPERTIES INCORPORATED

(Continued from Page 713)

Minnesota Mental Hygiene Association, and the University.

Dr. A. Alan Challman, of the University's Department of Psychiatry and Neurology, characterized mental illness as today's number one public health problem. There are not enough psychiatrists available to staff the community clinics often suggested by the public at present, he pointed out, and the training of more psychiatrists and psychiatric aids is one of the chief needs of the immediate future. Another great need is expansion of the research program in this field. At present, he said, only 25 cents a case is being expended on research, whereas thousands of dollars are spent on the care and treatment of each case.

Dr. Alexander G. Dumas, chairman of the Governor's Committee on Mental Hygiene, voiced the committee's recommendation that a five-million-dollar psychiatric institute be set up in connection with the Medical School of the University of Minnesota within the next three years, primarily as a training center for all types of psychiatric workers, including physicians, nurses, social workers, and attendants. Patients would be referred by their own physicians, and a continuous research program in acute treatments would be maintained.

Other physicians on the Institute program were Drs. Edward Dyer Anderson, C. A. Aldrich, Harold B. Hanson, Donald W. Hastings, Roger W. Howell, Reynold A. Jensen, Hyman S. Lippman, and Edmund W. Miller.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

NEUROANATOMY. Second Edition. Fred A. Mettler, A.M., M.D., Ph.D. Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University, New York. 536 pages. Illus. Price, $10.00, cloth. St. Louis: C. V. Mosby Co., 1948.

SUCCESSFUL MARRIAGE. Edited by Morris Fishbein, M.D., and Ernest W. Burgess, Ph.D. 547 pages. Price, $6.00, cloth. Garden City, N. Y.: Doubleday & Company, Inc., 1947.

SYNOPSIS OF PEDIATRICS. Fifth Edition. John Zahorsky, A.B., M.D., F.A.C.P. Professor of Pediatrics and Director of Department of Pediatrics, St. Louis University School of Medicine, and Pediatrician-in-Chief to St. Mary's Group of Hospitals, Fellow of American Academy of Pediatrics. Assisted by T. S. Zahorsky, B.S., M.D., Senior Instructor in Pediatrics, St. Louis University School of Medicine, and Assistant Pediatrician to St. Mary's Group of Hospitals. 449 pages. Illus. Price, $5.50, flexible binding. St. Louis: C. V. Mosby Co., 1948.

HISTORY OF THE MEDICAL SOCIETY OF THE COUNTY OF WESTCHESTER, 1797-1947. A compilation from the available minutes of the Society and various contemporary sources during the years for which the minutes were lost. 193 pages. Cloth. White Plains, N. Y.: Medical Society of the County of Westchester, 1947.

THE METROPOLITAN LIFE: A STUDY IN BUSINESS GROWTH. Marquis James. 480 pages. Illus. Price, $5.00. New York: The Viking Press, 1947.

The story of the Metropolitan Life Insurance Company parallels the development of life insurance in this country. Since medicine and life insurance are mutually

related both from the standpoint of risk evaluation and the public health and educational programs fostered by this company and others, the book should be of interest to many physicians.

LEO A. NASH, M.D.

OFFICE TREATMENT OF THE EYE. Elias Selinger, M.D., Attending Ophthalmologist, Mount Sinai, Cook County and Michael Reese Hospitals. 542 pages. Illus. Price, $7.75. Chicago: The Year Book Publishers, Inc., 1947.

The author has outlined and discussed the many procedures used in the ophthalmologist's office. The material is concise and well organized. The author presents many new and clever procedures used in office practice. This book is especially recommended to the ophthalmologist beginning private practice.

FRANK ADAIR, M.D.

TUBERCULOSIS AND THE FAMILY DOCTOR

Much could be learned about the epidemiology of tuberculosis if we could encourage the participation of more general practitioners in field studies throughout the country. The routine use of the tuberculin test on every person who visits the rural doctor's office would uncover a surprising number of hidden and unsuspected cases of tuberculosis.

The examination of family contacts and a search for the original spreader lead the family physician away from his relentless daily routine into exciting by-paths of epidemiologic investigations. Through the utilization of modern methods of diagnosis and follow-up, the rural physician extends the frontiers of knowledge of this puzzling disease.—HERMAN E. HILLEBOE, M.D., *Journal-Lancet*, June, 1947.

MAY-O-LITE...and 5/1,000,000 of an inch... Prevent a "Headache"!

Do your patients complain that night driving is a "headache"? Are they confused by lights . . . lights coming at them . . . lights behind them . . . street and intersection lights . . . and neon signs of every color? Are they still blinded, even though the lights of an approaching car are lowered?

For centuries, reflected light upon the surface of spectacle lenses has been a problem to many people. Since Roger Bacon, in the 13th century, first conceived the idea of improving faulty vision by constructing a pair of spectacles from magnifying glass, surface reflection has been one of the greatest handicaps of those who wear glasses.

Now, through the development of MAY-O-LITE, these surface reflections on spectacle lenses can be up to 95 per cent eliminated! MAY-O-LITE is a special vacuum coating applied 5/millionths of an inch thick to the lense surface.

By recommending MAY-O-LITE lense coating to your patients . . . you not only save them many night-driving "headaches" but you also help minimize their eye strain and improve their image definition.

Write today for a descriptive pamphlet and a treated sample of glass.

Thank You Doctor!

You registered physicians have done it again. The June class for our one-year course in psychiatric nursing was **oversubscribed,** a full month ahead of time, and is closed. The hospital extends its appreciation for the co-operation rendered by the doctors. Very gratifyingly, each time that the school has invited recruits your help has been forthcoming generously and promptly, not only by actual referrals of young women who became students but also by the good word passed along to encourage potential candidates to join this professional group.

On all sides we hear with pleasure that hospitals and doctors are findings places in their organizations and offices for our graduates and that the latter, the most capable of whom usually are the ones who come doctor-recommended, are playing important and responsible roles in nursing. Doctors operating their own hospitals in smaller communities of the upper midwestern states say they want more personnel with this fine training and with such loyalty and eagerness to serve.

The September class is being made up. Nominate without delay any young woman for whom you have a preference. We will send her and you a booklet. Prompt action insures sufficient time for the correspondence and clerical details pertaining to enrollment.

BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri-Maltose.

Reliance on MAPHARSEN is reflected in its extensive clinical use—over 200,000,000 injections since 1940. The significant advantages of high therapeutic effectiveness and notable relative safety have established its value as an antispirochetal agent. Clinical and serological follow-ups continue to demonstrate its high percentage of cures. Equally adapted to intensive, intermediate or conventional prolonged treatment schedules, alone or with penicillin, MAPHARSEN is an arsenical of choice in the treatment of syphilis.

MAPHARSEN®

LOOKING TOWARD NEW HORIZONS

The day of adventure and experimentation is by no means past. But current accomplishments are often overlooked in the zeal to scan the horizon for something better. It's sage advice that suggests that we take advantage of and nail down the present maximum accomplishments. It is also sage advice that suggests that you turn to your Society's investigated and tested plan of Accident and Sickness Insurance. The horizon holds no greater value.

Income protection should have priority over all other forms of insurance, for you are not able to maintain anything that you own nor reach that Utopia without income.
Please call us today.

For surface infections . . .

Impetigo and ecthyma usually respond rapidly to topical Furacin therapy. Good results have been reported in 49 of 55 cases of impetigo[1,2,3] and in several cases of impetigo about infected wounds.[4] Ecthyma responded favorably in 19 of 24 cases.[1,2] Cure of these pyodermas is often effected within eight days. Furacin N.N.R., brand of nitrofurazone, is available as Furacin Soluble Dressing and as Furacin Solution, both containing 0.2 per cent Furacin.® These preparations are indicated for topical application *in the prophylaxis or treatment of infections of* wounds, second and third degree burns, cutaneous ulcers, pyodermas and skin grafts. *Literature on request.* **EATON LABORATORIES, INC., NORWICH, N.Y.**

Diagnosis
WITHOUT *Disturbance*
in cholecystography

When gallbladder pathology is suspected, accurate roentgenologic demonstrations of normal, malfunctioning and calculous organs afford decisive information to physician and surgeon.

PRIODAX

(brand of iodoalphionic acid)

convenient oral contrast medium for gallbladder visualization, permits precise diagnosis by a simplified technic causing little or no discomfort to most patients.

Six 0.5 Gm. tablets after a light, usually fat-free evening meal constitute the sole preparation required for PRIODAX* cholecystography. No involved dietary prescriptions or adjuvant premedication with alkalies, pressor agents or paregoric are necessary.

PACKAGING: PRIODAX, beta-(4-hydroxy-3,5-diiodophenyl)-alpha-phenyl-propionic acid, is supplied in envelopes of six 0.5 Gm. tablets, available in boxes of 1, 5, 25 and 100 envelopes, each bearing instructions for the patient. Hospital Dispensing Packages contain 4 rolls of 250 tablets each.

MEAT

And the Dietary of Pregnancy and Lactation

According to a study published in the recent past[1] it has been shown that nitrogen balance is suddenly reversed from positive to negative shortly before term. This negative balance is further intensified by substantial losses of nitrogen during parturition and the postpartum period. Lactation imposes still another burden on nitrogen metabolism.

This study again emphasizes the need for a diet rich in biologically complete protein during the latter half of pregnancy. In this manner, the physiologic loss of nitrogen at term can be compensated, avoiding negative nitrogen balance. A high protein diet has the further advantage of producing a more copious milk supply.

In another recent publication,[2] the prevention of the toxemias of pregnancy by dietary means was stressed. Foremost among the measures recommended was a diet rich in high quality protein to assure nitrogen balance.

Meat is an outstanding source of protein in the dietary of pregnancy and lactation for these four reasons: (1) It is notably rich in protein, from 17 to 20 per cent of its uncooked, and from 25 to 30 per cent of its cooked weight; (2) The protein of meat, regardless of cut or kind, is biologically complete; (3) The appetite appeal of meat is high, and (4) All meat is of excellent digestibility—from 96 to 98 per cent.

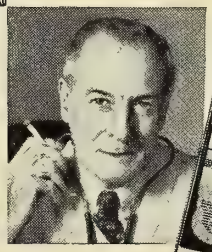
Experience is the Best Teacher

William Withey Gull

(1816-1890)

proved it in pathology

SIR William Gull is medically recognized for his many original observations which led to his classic description of myxedema and a greater understanding of nephritis. He also added much to the fundamental knowledge of neuropathology—such as his observations that locomotor ataxia was a disease of the posterior columns of the spinal cord. Medical knowledge was greatly enriched by Gull's experiences.



Experience is the best teacher in cigarettes, too!

Yes, Experience is what counts—just as it always has. And with millions of smokers who have tried and compared many different brands of cigarettes, Camel is the "choice of experience."

Try Camels! Discover for yourself how the rich, full flavor of Camel's choice, properly aged and expertly blended tobaccos pleases your taste. See if Camel's cool, cool mildness isn't mighty welcome to your throat.

Let your own experience tell you why *more people are smoking Camels than ever before.*

R. J. Reynolds Tobacco Co.
Winston-Salem, N. C.

According to a Nationwide survey:

More Doctors Smoke CAMELS

than any other cigarette

Three independent research organizations in a nationwide survey asked 113,597 doctors what cigarette they smoked. The brand named most was Camel!

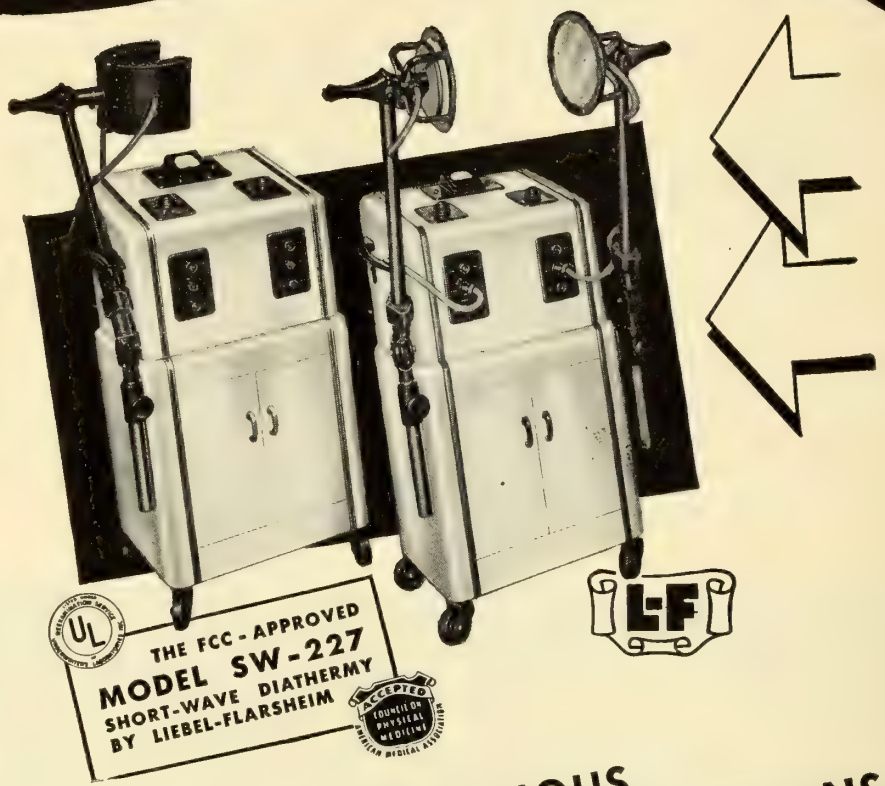
An Effective Adjunct in the Treatment of Certain Types of Tuberculosis

As an adjunct to conventional therapy, clinical experience has indicated that Streptomycin is the most effective chemotherapeutic agent in the treatment of certain cases of tuberculosis. In selected cases, Streptomycin has been found effective in shortening the period of disability.



The new, improved form of this valuable antibacterial agent—Streptomycin Merck (Calcium Chloride Complex)—provides three noteworthy advantages: (1) increased purity, (2) minimum pain following injection, and (3) uniform potency.

Write for the New Booklet
"STREPTOMYCIN IN TUBERCULOSIS"

Recently published, this booklet presents abstracts of the two authoritative reports which appeared in *The Journal of the American Medical Association,* November 8, 1947, showing the results of the use of Streptomycin in more than 900 cases of tuberculosis. It will be mailed to you on request.

The First Anesthesia . . .

Medicine and Dentistry thank Crawford W. Long (1815-1878), a Georgia physician, and Horace Wells (1815-1848), a dentist, for their pioneer work in the development of modern general anesthesia.

In 1842 Long observed the effects of commonplace "ether jags" upon the younger set—the boys who "imbibed" too heavily often injured themselves by stumbling over chairs and bumping against sharp obstructions; but, remarkably, they never seemed to experience *pain.* Long gave ether to a tumor patient . . . operated successfully . . . and painlessly. Then, in 1844, Wells followed with history-making proof of the value to surgery of *nitrous oxide.*

Long and Wells—and Morton and Jackson, two other famed figures in the early development of ether and "laughing gas" as general anesthetics—had to work *without protection* . . . without defense against allegations of malpractice.

Doctors Today are more fortunate—in the Medical Protective policy they have found *complete* protection, *preventive* counsel and *confidential* service.

Means more stable penicillin

● **MOISTURE CONTENT TEST—one of the 138 separate tests made by Abbott in the production of dependable penicillin:** A quantity of penicillin powder is weighed to the ten-thousandth part of a gram in a stoppered bottle which has been previously weighed. Then the stopper is removed and the bottle with its powder is placed in a drier under a vacuum of less than 3 mm. of mercury. Normal atmospheric pressure is 760 mm. The bottle remains in the drier for 12 hours at 55° C., with phosphorous pentoxide as a desiccant. When the drying period is completed, the bottle is removed from the drier, restoppered, cooled and reweighed. The loss in weight of the powder is considered moisture loss. Lack of moisture is a primary factor in preventing excessive decomposition of the powder; high moisture content tends to increase decomposition. The F.D.A. limit for amorphous penicillin salts is 2½% moisture content; for crystalline salts 1½%. Any lots which exceed those limits are rejected.

● Nothing is left to chance in the production of Penicillin Abbott. Numerous tests—138 in all—are made on such factors as potency, sterility, pyrogens, toxicity, penicillin G content, heat stability, pH, moisture content, solubility and crystallinity. These 138 Abbott tests, exclusive of those conducted by the Food and Drug Administration, make it possible for you to use Penicillin Abbott *with confidence.* Such dependability makes Abbott Penicillin Products a reassuring choice—whether your prescription calls for penicillin in cartridges, vials, troches, tablets, *Dulcet** Tablets or ointments. If you wish descriptive literature, just drop us a line. ABBOTT LABORATORIES, NORTH CHICAGO, ILLINOIS.

put *Summer Safety* in your formula prescription

Adding cooled boiled water to BIOLAC—as her physician directs—is the only precaution that a vacation-minded mother need take when preparing her infant's formula during the summer months. This simple procedure not only facilitates formula preparation, but also minimizes the possibilities either of contamination under adverse travel or resort conditions, or the chance omission of needed vitamins, carbohydrates or iron. BIOLAC, when supplemented by vitamin C, is a complete infant food. In readily assimilable form, it dependably provides all the essential proteins, vitamins, minerals, carbohydrates and other nutritional factors needed for optimum health.

Biolac dilution is easily calculated—quickly prepared: 1 fl. oz. Biolac to 1½ fl. oz. water per pound of body weight.

Biolac is a liquid modified milk, prepared from whole and skim milk, with added lactose, and fortified with thiamine, concentrates of vitamins A and D from cod liver oil, and iron citrate; only vitamin C supplementation is necessary. Evaporated, homogenized and sterilized. Available in 13 fl. oz. tins at drugstores everywhere.

DISTRIBUTION OF GENERAL PRACTITIONERS AND SPECIALISTS

WILLIAM DUNCAN, M.D.

Webster, South Dakota

TO THIS audience it should be unnecessary to report that there is a growing interest in the present problems and the future of the general practitioner.

Attention to this important subject no doubt has been aroused chiefly by two things:

1. The diminishing number of general practitioners in rural areas, notably in the small towns which in former years had one or more physicians.

2. The relatively rapid increase in the number of certified specialists, and also the large number of medical students and physicians discharged from the armed forces who have indicated their intentions of becoming specialists.

There are at present sixteen approved examining boards in medical specialties, and some of these now provide for examinations in subspecialties. As of March 1, 1947, a total of 28,476 certificates had been awarded by the various boards. This figure includes those who have died and those who have retired from practice. However, the "Directory of Medical Specialists" lists 24,028 specialists certified prior to November, 1945, and this figure represents only those living at the time of publication in 1946, although it does include those retired from active practice. On the other hand, only two of the sixteen boards were incorporated prior to 1930, so it should be fair to assume that with the numbers added since November, 1945, there are approximately 25,000 living and active certified specialists in the United States. A recent estimate from the American Medical Association indicates that the total number of practicing physicians is 160,000.

In other words there is one specialist for each 6.4 physicians in this country, and that ratio is evidently getting larger.

From March 1, 1946, to the same date in 1947, 2,404 certificates in specialties were awarded. The number of medical school graduates during a like period, June 1, 1946, to June 30, 1947, was 6,389 (this figure represents a period of thirteen months and includes ten schools which graduated two classes during that time, hence is relatively larger than an average year). Even so, the present ratio, as indicated by these latest figures, shows that for each specialist certified there were only 2.6 medical students graduated.

These figures are not being given necessarily to prove anything in particular, but they do show a definite, if not overwhelming, trend toward specialization, and everyone cannot be a specialist if we are to maintain our present concepts of the practice of medicine.

At the last annual assembly of the Omaha Mid-West Clinical Society in October of this year, a round-table discussion was held on the subject, "What is being done about the present problems and the future of the general practitioner." Among other subjects, overspecialization was discussed, and some very good points on this were brought out by Mr. M. C. Smith, executive secretary of the Nebraska State Medical Association.

The same subject was discussed at a recent meeting of the Association of American Medical Colleges. It was shown there that at least some of the specialty boards are becoming quite con-

Presidential Address presented at the North Central Medical Conference, November 23, 1947, Saint Paul, Minn.

cerned about the present trend and are hoping that in some way it might be stemmed to a certain extent.

From what has been said it would seem that we are facing a problem of overspecialization, or too many specialists. On the other hand perhaps this could rather be looked upon as a problem of too few general practitioners. We all know that there is still a great demand for specialists, especially in certain categories and in certain parts of the country. There are definitely not too many specialists in South Dakota; quite a few more, properly distributed or located, could be very useful, not only to themselves, but to the general practitioners now there and to what, after all, is the most important of all, the people of South Dakota. (This should not be interpreted to mean that the people of South Dakota are *suffering* from lack of medical or specialists' care, but to many of them it not only entails great inconvenience, but also, to my way of thinking, unnecessary hardships in order for them to reach certain types of specialists—notably ophthalmologists, otolaryngologists and psychiatrists.)

Consequently, with specialists as well as general practitioners, perhaps the really great problem is that of proper distribution.

This brief discourse was in no way intended to state a problem and then point out the solution.

However, a few suggestions pertaining to the solution will be offered:

1. The AMA or the Advisory Board for Medical Specialties should make an attempt to determine the optimum number of specialists needed. This, of course, should include not only the number of each type needed, but also (and of the utmost importance) *where* they are needed.

Naturally this would be quite an undertaking, but it should not be too difficult. The armed forces had definite, even though misguided, ideas about how many physicians they should have for each 1,000 men. Also Procurement and Assignment Services worked out their problems on the basis of ratios, one physician for each 1,500 civilians.

2. The same thing should be done concerning general practitioners, that is, determine the optimum number needed and again *where* they are needed.

3. This information should always be kept up to date, and it should also be given great publicity among medical students. In fact, at least a few lectures on the subject could well be given to the senior class, with great emphasis being placed on where they are needed.

4. Medical schools might very well arrange their curricula to allow for considerable more time in teaching medical history and ethics. For example, how many medical students have been taught the precepts of Hippocrates, especially the following one? "Sometimes give your services for nothing, calling to mind a previous benefaction or present satisfaction. And if there be an opportunity of serving one who is a stranger in financial straits, give full assistance to all such. For where there is love of man, there is also love of art. For some patients, though conscious that their condition is perilous, recover their health simply through their contentment with the goodness of the physician. And it is well to superintend the sick to make them well, to care for the healthy to keep them well, but also to care for one's own self, so as to observe what is seemly." It would not hurt to point out that medicine had its origin in the ancient temples, and although the teaching of medicine is now practically completely separated from religion, it is still based entirely on service to mankind. It has been said, "The right to serve is man's one freedom that must never be denied. For out of free men's devotion to their self-appointed tasks have come the great gifts to all mankind."

There could be nothing wrong with attempting to instill in these students more of the higher values in life, and especially to keep before them this question, "Where am I needed?"—not just "Where do I want to go?"

5. As for the specialty boards, they might consider two things. One, encourage these young men to go out into general practice for a while. Arrange in some way to give them some credit for a few years in that type of work. Do not restrict them on age. Enough of them will no doubt return to become specialists, and perhaps a few of them will learn to love their work and the people they serve so well that they will stay in general practice. Those who go out and then return might even become better specialists than otherwise, for I am sure that quite a few of our most eminent specialists started out in general practice.

COMMUNITY LEADERSHIP BY PHYSICIANS

THOMAS A. HENDRICKS
Chicago, Illinois

ABOUT the most delightful experience that life brings is a visit to one's birthplace. Today, as a representative of the Council on Medical Service of the American Medical Association, I am enjoying the nostalgic, though vicarious, thrill of a homecomer, for it was here at the North Central Conference that the idea and the propulsive force originated some four years ago, which brought the Council into being.

As I stand here, I see many who first sponsored the idea and then fought it through the House of Delegates. Last year at your meeting we reviewed a bit of the history of that battle. This year we hope in some way to express the gratitude that a son owes to a parent, and to have a family discussion of the problems facing the Council on Medical Service as it comes of age and perhaps determine just what function that Council can best perform for American medicine.

It was here too that the Council's medical regional conference was born, for it was your group which held the first modern medical economic regional conference. These regional conferences, developed nationally by the Council, have become recognized as functional units of American medicine, and have done much to make national, state and county medical societies efficient, effective, vital, driving forces in the medical life of America. These regional conferences have kept the physicians of America informed as to what the AMA is doing, but, far more important, they have kept the AMA in touch with the desires, wishes, hopes, ideas and ideals of the individual physician.

Here lies the source of the Mississippi River, at the start merely a trickle. By the time that trickle reaches the sea it has become a mighty giant, our Father of Waters—Old Man River—fertilizing and influencing much of our national life. So, our regional conferences, which started here as small, informal get-togethers, attended at first by a handful of state society leaders, have grown into conferences of formidable force and influence.

Not only have these conferences grown in size, they have become enlarged in concept, and in some regions have attained a status of permanency. The Middle Atlantic states have developed a regional organization with a constitution. At the recent Southeastern Regional States session, where the health problems of twenty million citizens of eight southern states were discussed, a new approach to the regional conference was developed—participation in these round-table discussions by representatives of the public, *thought leaders* of that region, leaders of thought on rural, educational, industrial problems. From this conference has developed an interim committee which is to map out a program for the health of the citizens of that region and leave it up for action to the various state societies composing the region.

The Board of Trustees has asked the Council to correlate and integrate, insofar as possible, regional conferences on rural health and industrial health with the medical service conferences. This is being done wherever possible.

It is my personal feeling that wherever permanent organizations such as yours and that of the New England states exist, our conference be made a part of your conference whenever you desire us to participate.

I have mentioned the phrase "thought leaders." By that we mean the molders of opinion in each community. It is with this group that the medical societies should act, and action can only be effective if the local medical societies are the thought leaders and opinion molders in matters of community health.

To me, the keenest and at the same time the most jolting and disheartening criticism that has appeared in all the multitude of recent studies and surveys which have abounded with detracting comments in regard to the medical profession is not found in the voluminous records of the Wagner-Murray-Dingell bill hearings, nor statements by Boas, Falk or Michael Davis. All these are of minor importance, for American medicine and the American people can and will in time sift out the good from the bad, the effective from the emotional, and continue to do what medicine always has done in the past—give the American

Read at the North Central Medical Conference, November 23, 1947, Saint Paul, Minnesota.
Mr. Hendricks is secretary of the Council on Medical Service, American Medical Association.

people an increasingly expert and efficient medical service, the best received by any nation in any time in the world's history.

The remarks which disturb me come from Robert and Helen Lynd in their case history study of "Middletown," *Middletown in Transition.* Of course, we were particularly interested in these studies in Indiana because "Middletown," picked as a typical American city, is Muncie, Indiana. Figures, facts and conclusions in regard to the political, social, educational, professional and business conditions and life contained in that study will interest any reader, for some of the charges against Middletown's citizens apply to almost any American community.

The Lynd's say: "A point worth noting is the loss of intellectual leadership and independence of Middletown's doctors and lawyers. Some of Middletown's most ruggedly independent thinkers in 1890 were the local doctors, judges and lawyers. These men less often speak their minds, they become to a greater extent intellectually colorless and are sticking to their last making money like the rest of Middletown's businessmen."

Perhaps we can laugh off most criticisms, but this one strikes deep into the heart of every American. You may say a doctor is a fraud, is "cracked"; you may even call him a quack, but never call him colorless! We do not believe the Lynds are correct, but if doctors are losing their intellectual leadership, their independence of thought and expression and action—their color—it causes one to worry about the shape of things to come.

I believe it was this that Dr. Buie had in mind in his unusual and beautifully written paper, "For Manners Are Not Idle."* I would like to quote for you the last two paragraphs:

> Accordingly, outstanding qualities of estimable men are these: gentleness and courage, boldness and prudence, tolerance, reverence, confidence, stability, humility, wisdom, patience and honesty. I believe not only that possession of these qualities engenders good manners but that the exercise of good manners furnishes proper soil for the cultivation of these qualities. The two elements working together, not alone, I believe, would do much to allay those twin dreads of the world today: fear and want.
>
> Finally, we, in our profession, have been reared well. The code of ethics of our organization provides that "a physician shall be an upright man, instructed in the art of healing." Furthermore, he "must keep himself pure in character and conform to a high standard of morals and must be diligent and conscientious in his studies . . . conducting himself with propriety in his profession and in all actions of life." Perhaps no other group is in a more favorable position to exemplify the union of good manners and good faith.

Endowed with a formal education and background beyond that available to any other group in the community, experienced in daily intimate contacts with their fellow men as are no other individuals, the members of the medical profession are expected to have a conception of affairs, an analytical power, an outspoken independent viewpoint that gives warmth, expression, humor, philosophy and "color" to their communities. The physician more than any other person should have a decisive influence on the life, the thinking and the daily habits of the people.

Whether it be Middletown, Indiana or Iowa; Middletown, Wisconsin or Minnesota; or Midland, South Dakota—Middletown must never lose the grand tradition of personal, independent action and thought which we hope and pray characterizes the physician. The American medical profession must never backslide from the fearlessness and courage of its men who told their world what they thought and their world listened and molded its action accordingly.

Groundwork has been laid by American medicine for a great development in the health services for the American people. To state and county medical societies goes the credit for this progress. Most societies resume their regular schedule of meetings in the fall. These are essential services that each state and local society should supply for American medicine to perform with community leadership:

Basic Records.

Each society should have for immediate reference an accurate evaluation of the medical personnel and facilities in each of its communities. Definite facts must be had to answer many of the sweeping and often unfounded claims by those who advocate that the government take over medical practice.

Health Councils.

Many communities have found local health councils a medium through which physicians with other interested and responsible groups may further the health programs of their communities. The Council on Medical Service has prepared a brochure suggesting ways of forming these health councils. This is a preliminary

*Presidential Address, Louis A. Buie, M.D., President Minnesota State Medical Association, delivered at the ninety-fourth annual meeting banquet, July 1, 1947.

release on this subject and will be followed by further reports as reactions are received and evaluated in the light of actual experience as to the value of health councils. If you desire this publication, write to the Council on Medical Service.

Public Relations.

The American Medical Association has adopted a program for activity to bring these health services to the public:

Ten Point Program.—An important point of this program is the development of voluntary health insurance as opposed to compulsory sickness insurance.

"National Health Policy."—An equally important point in the Ten Point Program is the care of the indigent. A resolution on policy to be followed in meeting this problem was adopted by the House of Delegates at the Atlantic City Session. The "National Health Policy" was developed by the New Jersey State Medical Association and the principles of this program set up in New Jersey have now become a further guide for leadership by the profession. The Board of Trustees has referred the resolution to the Council on Medical Service for action. In considering this for state action, it may be well to keep in mind the development of local health councils.

Professional Relations.

Most important of all to a functioning state or local medical society is good professional relations as distinguished from public relations. Fundamental to good professional relations must be a good feeling and understanding among the individual physicians composing the medical society. The seven deadly sins to be avoided to have a functioning local society and the seven characteristics to offset them are: Inertia, offset by Enterprise; Reaction, replaced by Progress; in place of Cliques, Friendship; not Discord, but Harmony; less Provincialism and more Vision; instead of Smugness, Leadership; and to replace Defeatism, Courage.

Dr. Walter Martin's statement of the obligation and necessity for community leadership at the Southeastern Conference is a good one: "National organizations can carry on studies, accumulate data, establish standards and formulate plans but state and local societies to a large extent must implement these policies. Medical plans for a community must fit into community planning as a whole and into the community way of life, and they must be designed primarily for the benefit of the people and not the profession. Plans for improving medical care should be on a community-wide basis, should receive their primary impetus and sustained force from the community."

The Council on Medical Service, which as I said before had its origin here in this North Central Conference, has become an important instrument. The Council serves as the "sparky," the pilot planner for medical organization. The frankest and perhaps the most forthright statement concerning the function of the Council has not appeared in any formal report of the Council. It was made by Dr. Adson, vice chairman of the Council, at Atlantic City.

"A number of years ago some of us were the spearhead for a progressive movement within the American Medical Association. This Council is, to a great extent, the result of that movement. At that time we had certain things in mind for the Council to do. In general, our purpose was to implement the functions and activities of the AMA. But there were certain definite lines of activity which we felt needed immediate attention.

"One was to present the AMA to the state medical societies. In order to do this, we set up district meetings and called in officers and committeemen from the various states. . . .

"One of our first developments in the Council was the News Letter. . . . The headquarters office has developed what they call a Secretary's Letter.

"Another activity that we have entered into is the promotion of prepayment plans. We started the ball rolling in this and were charged with the promotional activity. AMCP (Associated Medical Care Plans), organized under our instigation, has now come along and taken over many of the details having to do with prepayment plans. . . . We must realize that these things are bound to happen as we create, prove and pass on or lose functions to others.

"We have tried to stimulate rural health, and now the House of Delegates has created a committee on rural medical service whose function it is to consider and develop plans along that line.

"Some time ago we discussed indoctrinating medical students in their junior and senior years of medical school. We spent some time discussing the creation of an Association of Medical Students, granting the students an associate membership, and making the *AMA Journal* available to them. Although the Council was unsuccessful in bringing this to pass, the suggestion was made by this year's incoming president that just such a policy be established, and his suggestion was approved by the House.

"If the Council is going to live and grow, and if we are going to hold the confidence of the profession that we have had, we cannot go to sleep. I think each one of us will have to keep his ears to the ground to get the pulse of what is going on around us. I feel that if the Council is going to live and contribute to medicine as we have attempted to do, we cannot sit still."

In this spirit of pioneering, in conclusion, I am going to hazard the following five proposals for your reaction. They have not been discussed

formally either by the Council or the Board of Trustees. Your criticism, comments and suggestions will be appreciated:

1. The publication of a book *Best Talks on Medical Economics for 1947*. Doctors are good pamphleteers, but they don't have time to write full-length books.

2. Appointment of subcommittees to put into action each point of the Ten Point Program of the American Medical Association.

3. Better use of local committees on medical service. Other subcommittees could be created under the Council, such as a subcommittee on voluntary health insurance, dealing with the entire field of prepayment; a subcommittee on professional relations, having to do with the news letters and the regional conferences. Then, in order to make this reorganization effective, that the state medical societies be urged to create or reactivate their committees on medical service. (Some of these are termed committees on medical service and public relations.) Perhaps even the county medical societies could be asked to create similar committees. From these state committees doctors would be selected to serve on the subcommittees of the Council on Medical Service. In this way we could maintain direct contact with the thoughts and ideas of both the state and county medical societies so that we might better assist them in carrying on effective community leadership. This type of reorganization would make the regular regional conferences more effective and would provide the Council with more continuous contact with both the state and county medical societies. While the Council on Medical Service, as it is now constituted, represents all parts of the United States, reorganization would expand this representation and provide for an even better distribution of thoughts and ideas.

4. Reorganization of the Council on Medical Service so as to have the following divisions and departments: (1) extension of medical care, (2) prepayment, in all forms, and (3) professional relations.

At Leavenworth and at the Army Staff College in Washington, studies are made and plans formulated for the defense of America in any eventuality: How would America be defended if the West Coast were invaded? What disposition of forces would be necessary if the East Coast were in the hands of the enemy? What plan of action could best be taken if invasion forces moved in through Mexico or Canada?

Teams are at work on each problem. Could not groups be set up to do the same for medicine? One group could work on each problem. How may the best medical care be made available if medicine were able to lay out its health program unhampered?

How may the individual integrity of the physician best be maintained if inroads are made by the Children's Bureau, by liberalization of the VA program to include dependents, which would make the government responsible for some forty million Americans?

What does all this add up to? Just this: Like Omar Khyam we keep coming out the same door that we went in—the county medical society—a door which must swing wide open to welcome all those who have health problems, and from whose portals must emerge men who are willing in these critical days to assume community leadership.

RATIO OF DISEASE TO INCOME

It will be noted that families with an income below $1,000 per year have nearly four times as much disability from tuberculosis, nearly three times as much disability from orthopedic impairments, and approximately twice as much disease and nervous disease as families with incomes over $5,000. For relief families, the ratio rises to nearly ninefold for tuberculosis, and fourfold for orthopedic impairments, between threefold and fourfold for rheumatism and digestive diseases. Considering all causes of disability together, the group with incomes under $1,000 shows 66 per cent more disability and the relief group shows 155 per cent more than the families with incomes over $5,000.—C. E. A. Winslow, D.Sc., Am. J. Pub. Health, Jan., 1948.

CAN THE LOCAL HEALTH CO-OPERATIVE FIT INTO THE VOLUNTARY PREPAYMENT MEDICAL CARE MOVEMENT?

L. S. KLEINSCHMIDT
Chicago, Illinois

IT SEEMS to me that a discussion of this subject is very fitting in the North Central Medical Conference here at Saint Paul. The six states represented in the Conference—Iowa, Minnesota, Nebraska, North Dakota, South Dakota and Wisconsin—are the center of an area where much impetus has been gained in the co-operative and consumer-sponsored movements, particularly in the rural phases, although they were not the first to undertake group action in attempting solutions to some of their problems. There are 1,625 local co-operative associations of all types reported in these states.

Again, in view of the forward-looking suggestions and actions that have served a real purpose in assisting to unify the thinking of the medical profession coming, I am told, from this conference in the past, it seems timely to discuss this subject today.

The problems suggested by this subject are a definite part of the medical profession's public relations problem and mesh with the other subjects on this program especially if our today's subjects are slightly restated as follows:

1. Physician's relationship.
   (a) With public agency medical care.
   (b) With veterans' medical care.
   (c) With consumer-sponsored medical service.
2. Meeting rural health service needs.
3. Establishing local health councils.
4. Leadership by physicians.

In reviewing the over-all relationship, this question is logical, "Can the local health co-operative fit into the voluntary prepayment medical care movement?" First, let us consider how new the consumer-sponsored medical service plans are and when the medical profession recognized their activities as voluntary prepayment plans?

The oldest plan so far reporting to us is the French Mutual Benevolent Society of San Francisco, California, organized in December, 1851. However, noticeable expansion did not develop until in the early 1930's. Approximately two-thirds of all consumer-sponsored medical service plans have been developed in the past nine years.

The Bureau of Medical Economics took notice of this development and in April, 1937, published an article in the *Journal of the American Medical Association* that was distributed as a reprint. This statement was made: "The co-operative movement is not new, although only in recent years has it begun to attract national attention." In 1941, the same bureau reported: ". . . There has been no opposition to the use of the principles of insurance purely as a means of meeting the cost of medical care when there was no interference with the quality of service."

The House of Delegates of the American Medical Association in 1943 established the Council on Medical Service and enumerated functions which read in part: "To make available facts, data, and medical opinions with respect to timely and adequate rendition of medical care to the American people; to investigate matters pertaining to the economic, social and similar aspects of medical care for all the people and to study and suggest means for the distribution of medical service to the public consistent with the principles adopted by the House of Delegates."

In 1945, the House of Delegates approved "a continuous survey of all voluntary plans for hospitalization and illness to determine their adequacy in meeting needs and maintaining continuous improvement in quality of medical service." During the same meeting of the House of Delegates, the Committee on Rural Medical Service reported in part: "Prepayment plans for medical care and for hospitalization have the approval of many farm groups; however, some of them feel that such plans should be consumer-operated. Such plans should be made available to farm groups as early as experience permits."

Additional discussion of co-operatives on the part of the medical profession occurred from time to time, reaching its height of interest following the conference of co-operative and consumer-sponsored health service plans held at Two Harbors, Minnesota, in August, 1946. During this conference, a national organization of these

Read at the North Central Medical Conference, November 23, 1947, Saint Paul, Minnesota. Mr. Kleinschmidt is a member of the Council on Medical Service of the American Medical Association.

plans, the Co-operative Health Federation of America, was organized.

In December, 1946, the Council on Medical Service reported it "is gathering information and data relative to the medical co-operative movement throughout the country." The Committee on Rural Medical Service reported that "the development of co-operative associations and other consumer-controlled groups for provision of medical care has received considerable attention. This is an interesting experiment in the rural effort to do something constructive from the point of view of the consumer. The medical profession should be concerned in all these plans with the view that a high level of medical care be supplied." The House of Delegates approved the study of these plans. It recognized that while there is some difference of opinion regarding the establishing of consumer co-operative medical care programs, nevertheless they are functioning in certain areas, and stated that in order to ensure good medical care certain basic principles be formulated.

Consumer-sponsored programs then date back ninety-six years in the United States. The American Medical Association has been particularly interested in their activities for the past ten years, the period of their greatest growth. The second point to consider may well be the size of these plans and where they are located.

In our discussion of these plans may I point out that the source of information is from the plans themselves. We expect to continue the study to check the information we have, and to obtain additional information at a later date from physicians in areas where these plans are in operation.

According to information so far gathered, we have knowledge of seventy-nine consumer-sponsored local health service plans. We have leads out that we believe may put us in touch with additional plans. The seventy-nine plans on our list are located in twenty-seven states and the District of Columbia. They operate in industrial areas, urban areas and rural areas. Where they do operate, they are supported by labor unions, by workers in a particular industry and by farm organizations. Usually they have been built in a given area by a particular group who have, or think they have, been faced with a lack of medical facilities and personnel or with an economic problem in meeting the costs of improved medical care or both.

Forty-eight of the seventy-nine plans show a total enrollment of 674,653 persons. Of these, 428,883 are urban and 245,770 (36.4 per cent) are rural coverage. If we should assume that the remaining thirty-one plans had an average enrollment similar to those reported, then the probable enrollment in consumer-sponsored and co-operative plans would total 1,106,000 persons.

Just to help visualize this enrollment, it might be compared with the enrollment figures of medical service plans. Medical society plans have actual enrollment six times as large as the probable enrollment of these consumer-sponsored plans. If we make average allowance for the medical service plans that have not given rural enrollment figures, the total persons enrolled from rural areas is about the same for medical service plans and for consumer-sponsored plans. Stated on a percentage basis of the total enrollment for each, we find 8.3 per cent of medical service plan enrollment is composed of rural subscribers, and 36.4 per cent of the enrollment in consumer-sponsored plans in rural.

These plans seem to be of sufficient size and importance to justify the serious consideration of the medical profession, especally their potential possibilities in rural areas.

As a third consideration let us turn to some of the characteristics of these plans.

Thirty plans have reported information in sufficient detail to permit classification according to some of their characteristics. All of the thirty plans have nonprofessional boards of directors to handle the business affairs of the association. Fourteen plans (46 per cent) have a medical board or a physician's committee to plan and direct the medical practice. Eight plans (27 per cent) have a contract with a physician or several physicians responsible to the board to handle medical practice. Eight plans have indemnity contracts and make no definite arrangements for medical supervision.

As to facilities used, sixteen plans have their own hospital or clinics, and fourteen plans use existing local facilities. In the matter of facilities the plans are about equally divided.

The tendency toward the service type of contract for medical care predominates. Twenty-one plans (70 per cent) write service contracts; eight plans (27 per cent) write indemnity contracts; and one plan (3 per cent) writes a combination of both. As a matter of comparison,

ninety medical society plans are about equally divided among service contracts, indemnity contracts and a combination of both.

All plans depend on legally licensed physicians to render medical care benefits to their members, and all indicate that they offer freedom of choice of physicians. This, of course, applies to those co-operating with or employed by the plan.

There are, however, four distinct methods under which arrangements are made with the physicians to render medical care and receive payment therefor. The plans are about equally distributed between these four methods.

1. Eight plans provide cash indemnity payments to the subscriber for the amount of his medical bill as certified by his attending physician or up to an amount in a schedule of payments for services covered in the benefits. The patient pays the doctor and is reimbursed according to the terms of his insurance contract. These eight plans, with a total enrollment of 224,390, are divided into three urban plans with 91,834 persons enrolled, and five rural plans, with 132,556 persons enrolled.

The Hoosier Farm Bureau Life Insurance Company of Indianapolis is an example of the indemnity type. It is a mutual company, organized by the Indiana Farm Bureau, that writes many kinds of insurance for its members, including surgical and hospital expense. The benefits include surgical expense up to the amount named in the schedule but not to exceed $150. The reimbursement for each patient-day in the hospital is $5 for members and $4 for dependents. Operating room, anesthesia and laboratory services are not to exceed $25 for members and $20 for dependents.

The cost for man and wife is $28.80 and for a family including all dependents is $40.80. During 1946, 55 per cent of the annual premiums collected were paid out in claims. In order for a county to enroll, 75 per cent of the Farm Bureau members must join. Thirty-nine thousand persons are enrolled in Indiana under this plan.

Incidentally, the Grange in Indiana is enrolling its members by counties on a similar basis, except that the coverage offered is Blue Cross hospitalization and Blue Shield medical service. The Grange enrollment is included in rural enrollment of the medical service plan sponsored by the Indiana State Medical Association. Here is a consumer-sponsored organization co-operating with a medical society and a Blue Cross program. The cost for a family including dependents is $48.60 per year. The additional cost of $7.80 per year is offset by more benefits for hospitalization. The Grange in twelve other states is reported as now offering Blue Shield and Blue Cross benefits to its members.

2. Nine plans pay the physician on a fee-for-service basis for medical care rendered to members. The total enrollment of this group is 114,160 and is made up of two of the larger urban plans, with a total of 98,605 persons enrolled, and seven of the smaller rural plans, with a total of 15,555 persons enrolled.

The Southeast Missouri Health Service, Inc., Poplar Bluff, Missouri, is an example of this type. It was incorporated in December, 1941. After agreements and operating principles were developed and an education program carried on with the people, service was started to members on January 1, 1943. It is consumer and medical society sponsored, with a seven-member board of directors to manage the business, and a medical committee appointed by the county medical society to direct the medical practice and approve medical bills for payment. Both boards agree on the extent of benefits, the rates to be charged the families, and the method of payment. It is a project of the medical economics committee of the Missouri State Medical Association.

At present, farm families with earned incomes of $1,500 or less are eligible. Plans are under discussion for extending the program to urban residents with incomes of $2,000 or less. The benefits include general practitioner's care, surgery, and hospitalization in a ward-bed up to twenty-one days for each person in any one year. Prescribed drugs and children's dentistry have been included, but these two benefits are being discontinued.

The maximum family payment is $60 and the minimum, $30, to become a member, with 6 per cent of earned income used as a basis of payment for families earning between $500 and $1,000 per year. The cost of this program on the basis of normal local fees was $99.94 per family. This cost was met by payments from the families that averaged $36.44, from tax funds supplied through

Farmers Home Administration, which averaged $33.73, and from the professions an average of $29.77 per family on the basis of accepting pro rata amounts or granting discounts from their normal fees. This substantial contribution on the part of the medical and allied professions made it possible for this program to continue to operate.

The distribution of benefits paid for the year July 1, 1945, to June 30, 1946, was: for medical care and surgery, 41.3 per cent; hospitalization, 25.7 per cent; drugs, 16.1 per cent; reserves, 2 per cent; administrative costs, 14.9 per cent, or about 85 per cent paid in benefits.

3. Six plans render benefits through contracts with a small group of physicians on a salary basis supported by local physicians on a fee-for-service basis. This group has a total enrollment of 243,152 persons. It is made up of four urban plans, with a total enrollment of 231,207, and two rural plans with 11,945 persons enrolled.

Since this group is largely urban, we have selected the largest one of the plans, located in New York City as an example. The Union Health Center was organized in 1913 by the International Ladies' Garment Workers Union and thirty-two locals, and started service to members in 1916.

The business is directed by a board of ten directors and the medical director. A medical council, composed of physicans and the medical director, hire the ten physicans on the staff, work out the arrangements with 100 part-time local physicians, and direct the medical activities. Union members and their dependents are eligible to receive service.

The benefits include medical care and all diagnostic services in the clinic of the Union Health Center on a service basis for union members. Surgery and hospitalization is also provided union members on an indemnity basis. These benefits cost the individual $18, with some variations between the local unions. Dependents of union members are supplied these services on the basis of reduced fees at the time medical service is received. Our reports indicate that subscribers pay 23.3 per cent of the total costs as cash payments and 55.8 per cent as employe payroll deductions paid through the local unions. The international organization pays 20.8 per cent, with .1 per cent from miscellaneous sources to make up the balance to cover the costs. The administrative costs of the prepayment features of the plan are absorbed by the unions and the clinic. All of the funds collected went to pay for services.

4. Seven plans have organized group practice with physicians on salary. All of these plans own their facilities. This group of plans have 36,804 persons enrolled. Two are urban plans with a total enrollment of 20,848, and five are rural plans with a total enrollment of 15,956.

As an example of this group, I wish to discuss the Farmers Union Hospital Association at Elk City, Oklahoma, organized in 1929 by the Farmers Union and Dr. Michael A. Shadid.

A board of five directors, elected by the membership, and Fred V. Shadid, M.D., medical director, manage the business and control the property of the association. A medical staff of six medical doctors and one dentist, together with the medical director, plan and carry out the medical practice, select the professional staff members and plan the budget required for benefits covered.

The benefits include medical care, surgery and hospitalization at the association's hospital. Extra fees are charged members for certain services. This extra fee for anesthesia and operating room is $20 for major operations and $10 for minor. Three dollars per day is charged for hospitalization and $3 for x-ray, et cetera.

The annual dues for a family including children is $34 and $6 additional for each dependent blood relative included in the certificate. In order to be enrolled as a member of this plan, each family must purchase a lifetime membership of $50 to apply on hospital cost and equipment.

The administrative costs of the prepayment plan are absorbed by the hospital and the Farmers Union.

Of these four types of payment arrangements discussed, the largest number of persons are enrolled under the one with full-time medical and clinic direction in co-operation with local physicians in carrying out the benefits of the plan. The one supplying medical service on an indemnity basis is the second largest, the one where local physicians co-operate on a fee arrangement is the third in size, and the one organized on a group practice basis is the smallest, having enrolled about 6 per cent of the total persons covered in these plans.

The consumer-sponsored plans are gradually undergoing revisions based on their experiences. It might be well to attempt here to enumerate some of the general characteristics and the trend of revisions observable.

1. Voluntary prepayment health service as distinguished from compulsory.

2. Variations in types of plans based on local determination.

3. Development largely with special groups in industry and on farms, which groups are faced with a health service problem which they think is not otherwise being met.

4. More or less flexible and have no fixed pattern or standards at present.

5. Trend toward more or less complete health benefits on a service basis.

6. The majority, even though they may operate on a different basis now, seem to favor group practice by physicians although their real interest centers on obtaining the service of specialists.

7. Establish own facilities in areas where there is a shortage of hospitals and clinics.

8. Lean toward salary or contractual arrangements with physicians.

9. Avoid the corporate practice of medicine (which is illegal) by "arranging to furnish medical care" for its members and not "guaranteeing to furnish the service."

10. Seek the co-operation of physicians and welcome the prospects of some type of standards being developed.

Where then "can the local health co-operative fit into the voluntary prepayment medical care movement?"

With so many local variations and personalities, it seems that "the place where they fit" requires local determination.

The jig-saw puzzle—as Charlie Crownhart has called the various types of prepayment medical care plans—needs to be fitted together. The co-operatives are part of that puzzle.

The physicians constitute the most logical group, if not the only voluntary group, which may be looked to as sufficiently interested in the puzzle of prepayment medical care and as capable of bringing it into a unity of purpose on a community basis.

DISTRIBUTION OF GENERAL PRACTITIONERS AND SPECIALISTS

(Continued from Page 746)

The other thing that specialty boards might consider is that in some respects perhaps they are too restrictive. The American Board of Surgery, for example, requires that one limit his work entirely to surgery before being eligible for certification. If that rule had been followed in the past we would have quite a few less diplomates of their board at present, and if it is held to in the future it cannot help but influence at least the distribution of competent surgeons if not their actual numbers.

In the latest volume published by the South Dakota Historical Society there is a biographical sketch of Dr. Theodore F. Riggs of Pierre. The final paragraph is a quotation from Dr. Richard W. TeLinde, chief gynecologist of Johns Hopkins Hospital: "I have known Dr. Riggs for twenty-five years, and he is an outstanding surgeon, in fact, I know of no one who does better general surgery in the broad sense than Dr. Riggs. The State of South Dakota can feel very happy that a man of Dr. Riggs' training and ability chose to spend his life in a frontier community rather than stay in one of the large cities. Since having a short professional association with Dr. Riggs twenty-five years ago, I have sent him an assistant from the Johns Hopkins Hospital almost every year. I happen to know that each one of these assistants regards Dr. Riggs as highly as I do." Dr. Riggs, of course, is not interested in becoming a diplomate of the American Board of Surgery, for he already is one. On the other hand, he would no doubt readily admit that his practice is not strictly limited to surgery, and so as of this day he would *not* be eligible to become a diplomate.

Some of the above suggestions may sound a little idealistic, but in this atomic age of international confusion and disillusionment we could all do much worse than attempt in every way to elevate our profession further and further toward the ultimate goal of American medicine: "The best medical care, made available to all the people—not only of these United States, but to all the world."

THE NEBRASKA STATE MEDICAL ASSOCIATION'S FEE SCHEDULE FOR PUBLIC AGENCIES

FLOYD L. ROGERS, M.D.
Lincoln, Nebraska

IN NEBRASKA, we are interested in our problem of public relations. We are particularly interested in the problem of the relationship between public agencies financing medical care and the medical profession. By public agencies, we mean agencies using funds derived from taxation and agencies directed by government. We are also interested in private agencies who enter the medical field, but these relations are largely private and will, to a very considerable extent, be influenced by our relationship with public agencies.

These agencies are on national, state, county, and local levels. They have, during recent years, been requesting an ever-increasing amount of medical service. In Nebraska, the profession has been asked to co-operate with public agencies to provide medical care for the categorical assistance group—old age assistance, aid to dependent children and blind; for vocational rehabilitation, maternal-child health, workmen's compensation, crippled children, veterans' aid, veteran out-patients, county and city indigents; and for inmates of city and county jails.

In every instance, these requests could be reduced to contain two fundamental questions. How can we best contact a large number of physicians for employment and *how* should they be paid? In the past, the profession in Nebraska has had no plan for dealing with these important groups.

Lacking such a plan, agencies have, of necessity, prepared plans for their own particular use. Naturally plans vary greatly. Various agencies employ physicians in various ways. These agencies pay various amounts. In the past, many agencies have employed physicians on full or part time basis. For the most part, salaries have been inadequate, considering the amount of work required. This, of course, has held taxes down but has led to inadequate services. Of recent years, these agencies have requested a more general employment of physicians. There seems to be a decreasing objection to free choice of physician and fee-for-service pay. There has come to exist in Nebraska a desire for a "fee schedule." This desire has repeatedly been expressed by members of our association and agencies, both public and private, interested in providing medical care. In general, the thought has been that a "fee schedule" would result in uniformity and fairness of fee where confusion has existed. A "fee schedule" should include a sufficiently complete listing of medical procedures to make it serviceable in the many fields where it would be used, together with fees that would be fair and average. Fees paid from public funds certainly should not exceed the usual fee in the community for private patients. Such a schedule should be acceptable to physicians and to those responsible for paying. Its general use by agencies, governmental in particular, would have many obvious advantages; and such a schedule should come as an effort of the medical profession.

Our state agencies now pay varying amounts for similar services. County fees for medical care differ to a ridiculous degree. These schedules, for the most part, have been prepared by laymen representing the agency, together with a physician or physicians employed by or particularly interested in the agency. The medical society or the profession in general has not been consulted.

In many instances, these schedules have been fair and just, seldom have the fees been excessive, and often they have been too low. When the fees are too low, doctors may react in several ways. In case the recipient is indigent, the physician, with few exceptions, accepts the responsibility and renders adequate service regardless of fee. The feeling of responsibility to those unable to pay has always been strong in the minds of physicians, although it is unreasonable to expect this responsibility for the community.

In other instances, physicians react in a less honorable manner where small fees are paid. Often devious methods are used to increase the fee. Mileage is charged for each call although several calls are made on one trip. Taking the temperature and blood pressure is called a com-

Read before the North Central Medical Conference, November 23, 1947, Saint Paul, Minnesota. Dr. Rogers is chairman of the Planning Committee, Nebraska State Medical Association.

plete physical examination. Where small fees are paid for physical examinations, the examinations are likely to be worth very little. One agency paying a two-dollar fee requests a history, physical examination, including examination of heart, lungs, abdomen, nose, throat, vision—near and distant, with and without glasses—hearing, blood pressure, various measurements, and urine analysis, with ample space for confidential information which will be held in strict confidence.

Often the recipient, under ordinary circumstances, is the physician's private patient. Here the physician usually renders adequate service, and accepts the reduced fee to avoid embarrassment. Also, often the number of cases treated for an agency are few, and the course of least resistance is to do the work, accept the small fee and not make a fuss.

One question that constantly offers agencies difficulty is that of deciding just what a given medical service implies. For instance, what is a physical examination and what is a fair fee? This, of course, depends on the complexity of the problem which the patient presents, on the ability of the physician to deal with it, and on his desire to do so. Likewise, surgical and other procedures vary much but offer somewhat less of a problem.

This confused state is not alone the fault of the agency; the medical profession has failed to offer constructive leadership. Our medical schools and medical societies have grooved us to a certain pattern. This pattern emphasizes doctor-patient relationship. We must think more about well people and what well people think of us—in particular, what large groups of well people think. It is the well people who make the laws. Our public relations must be improved.

Painful as it is to admit, we *must admit* that a small minority of our profession are dishonest. They strive to get the most and do the least where a third party pays the bill. How to work this third party into the picture is our question. We have not wanted him, but society says he must be there. We must provide leadership and must discipline our own ranks.

With these problems in mind, the 1944 House of Delegates of the Nebraska State Medical Association instructed its planning committee to prepare a "fee schedule" with the hope that it would be uniformly used by agencies paying for medical care from public funds. This was definitely not to become a "fee schedule" for private practice. You would not benefit by a long tabulation of our ups and downs in this effort. However, some steps in the completion of this schedule should be related.

We considered a schedule complete over a year ago, only to find it lacking in some important respects which caused us to discard it, although preliminary printings had been made. We have held numerous deliberations with general practitioners and specialists from various parts of the state. We have been mindful, in particular, where special groups have set up "fee schedules" either on state or national levels. Many schedules from other states, particularly adjoining states, have been reviewed, and an effort toward conformity has been made. Several agencies have already used the schedule in various stages of its development, and its shortcomings have been noted and plausible changes made. It has been through the grind of negotiations with the Veterans Administration. While our state association does not have a completed contract with the Veterans Administration, as far as we know, the schedule has not been an objectionable feature to officers of the administration. Also we should state that the system of numbering, much terminology, and other features are those used by Veterans Administration. Some of our fees are higher and some lower than those of surrounding states. Likewise, our schedule varies somewhat from Veterans Administration schedules as used in other states. These differences for the most part are only slight.

Any schedule which will serve for all the various agencies and various localities cannot be brief or simple. The number of procedures must be large. A system of numbering must be used which will make future necessary alterations possible without disturbing the whole numbering system. For convenience, certain procedures are listed in more than one place. Also for convenience, the first part of our schedule is a rather short list of commonly used procedures, followed by a more lengthy and complete list.

A most difficult problem has been that of fees for specialists. The difficulty is in particular that of *who* is a specialist.

The profession in Nebraska is at this time unwilling to accept wholeheartedly American Board members as the only specialists. The dis-

tribution of certified board members is not sufficiently wide to serve all parts of the state. We must have some answer. While certification is our best answer, a specialist must not be too rigidly defined at this time.

A "fee schedule" should have a feature of flexibility. A schedule could be much more simple if this flexibility were not required. Various conditions exist in different agencies and in medical practices in various parts of the state. Some agencies in certain counties do not have sufficient funds to pay other than limited fees at this time. Federal funds are less limited, and the state, due partly to Federal matching, is also less limited. Also it is not inherent in people to be uniform. Regardless of income brackets, families vary greatly in how they wish to spend their money. Some spend much for home, some for entertainment, and some a relatively large proportion for medical care. Flexibility must be a feature if this schedule is to endure general economic changes. A fair fee for 1932 is not a fair fee for 1947. We have certainly not reached the goal of an honest dollar.

This "fee schedule" provides flexibility by use of a unit system. Every reasonable effort has been made to establish a proper relationship for the various services. This relationship is expressed in a number of units. Without doubt we have made errors in establishing this relationship. Much just criticism could be offered; but only time, experience and co-operation will correct these errors. This matter of relativity is the fundamental foundation of any "fee schedule." Changing trends and methods of practice will indicate futher change. A procedure which is difficult and time consuming today may be made relatively simple in the future, and thus justify a smaller relative value and smaller evaluation in a smaller number of units and thus a lower fee. With the various procedures expressed in units, the whole schedule can easily be adjusted to the various circumstances without disturbing its fundamental relative values. Many will object to the unit system as too complicated and as unnecessary.

However, we must keep in mind that there are three steps to arriving at a just fee. First, what service was rendered; second, what is a fair relative value in relation to other services; and, third, what is the ability to pay in these times. Where only two parties are concerned, the patient and doctor, the matter is relatively simple. Where three parties are involved, the patient, the doctor and an agency, complications are more likely. Much good surely will come if we of the medical profession take constructive leadership in providing a workable system which has both a feature of advantageous uniformity and necessary flexibility. At the present time, it is considered practical to place the value of the unit at 10 cents. The amount of this fee is included in this schedule.

Any doctor or groups of doctors are, of course, free to make agreements with the various agencies; however, we are urging our members to use this "fee schedule" in dealing with public agencies. The value of the unit can be adjusted to any level by the doctor or doctors and the agency. It may be changed by them from time to time, depending on the various factors.

One of the present committees or a new committee of the state medical association should serve as a clearinghouse for this effort. They should receive at state medical headquarters information as to contracts and placing or changing of unit value. They should receive suggestions of all kinds from doctors and agencies. In particular, they should receive suggestions as to changes in the relative value of various services, that is, a change in the number of units credited for the services. The committee should analyze and digest this material. Annually they should report to the House of Delegates. Their report should include suggestions in regard to changes in the unit value for various services.

Then the House of Delegates should have the sole responsibility and authority to change unit values. The planning committee is suggesting changes in our by-laws which will put this into effect.

Another step which would have many advantages would be that of uniformity in the blanks used by the various agencies. There is no reason why a small and a proper assortment of blanks would not fill all needs. Familiarity with a blank on the part of the physician makes for better and more prompt reports. Familiarity with all the present blanks is impossible. Only preliminary steps in this have been made. Also a uniformity of requests for service and methods and time of payment should be part of the plan.

We must be ever mindful that, while we want

(Continued on Page 826)

A PLAN FOR ESTABLISHING LOCAL HEALTH COUNCILS

FRED STERNAGEL, M.D.
West Des Moines, Iowa

THE Interprofessional Association of Iowa, composed of physicians, dentists, veterinarians, nurses and pharmacists, was organized thirteen years ago for the purpose of promoting better interprofessional relations. Recently the executive body of this organization felt that, in the light of national developments, we must in some way contribute also to better public relations for our professions. We realized the truth of the statement that in order to encourage better public relations, our organizations must first do good, then tell the world about it. There is no question that our professions are doing good, but most of the people don't know or are badly informed about what we are doing. Last winter the division of health education of the Iowa State Department of Health, which has a full-time traveling director, came to us and solicited our cooperation in a plan for conducting health forums throughout the state. This seemed to be the opportunity we were waiting for, and accordingly we accepted the suggestion to pool our efforts and facilities toward health education, because recent public polls have indicated that the public is more interested in health topics today than in anything else.

All good citizens are interested in the health and welfare of the people in their community. Individually, the layman pays little attention to good health until he loses it, and then he fights to regain what he has either lost or is about to lose. But collectively, every community has a certain group of public-spirited citizens who are continually seeking to improve the conditions for their neighbors, and many organizations have health committees, but these health committees, in most instances, are working in opposite directions. Their efforts need correlation and unified direction.

Last winter the Iowa Interprofessional Association and the Iowa State Department of Health discussed the possible projects and activities that might be adopted for promoting better correlation in health activities, and all in attendance agreed to the facts stated in the preceding paragraph. Health education in a specific, concrete, controlled form was pointed to as one of the needs for the average citizen in Iowa.

There was also a feeling among those present that specific contributions on the part of the membership of the Iowa Interprofessional Association toward a unified plan of health education would bring the professions so represented closer together and would impress upon the public their desire to help in solving health problems from the community point of view as well as from the professional service angle.

After a thorough and complete discussion of the possibilities of uniting the efforts of both the Interprofessional Association and the Iowa State Department of Health in the work of health education, it was agreed that such a plan would accomplish much, particularly since the health department was already set up to do such work and the Interprofessional Association had the talent to supplement such a program.

The purpose was to bring to the citizens of the state, facts that every layman should know, to answer the questions many individuals have regarding health, and to clear up many of the misconceptions that are current among the laity. Through the correlation of our efforts, this service would be possible.

The following steps were taken in the original plan, although occasionally in its execution a readaptation of procedures has to be made to fit the needs of the local community and the area in which the health education forum is to be presented. For your information, however, we present the original idea.

A definite community is selected for a health education forum based upon the interest of the local citizens. The director of public health education of the state health department, who does all the work of promoting and organizing the program, pays a visit to that community and discusses with the local leaders the opportunity for having a health education forum. During this visit those present are informed by the director that the Iowa Interprofessional Association, composed of doctors, dentists, veterinarians, nurses and pharmacists, is co-operating with the Iowa State Department of Health, and both of

Read at the North Central Medical Conference, November 23, 1947, Saint Paul, Minnesota.

Dr. Sternagel is a member of the Executive Council of the Iowa Interprofessional Association.

these agencies are ready to supply speakers for any community health meetings they may have in mind. For this purpose they are given a list of about fifty subjects to choose from. The committee then selects the topics they desire to have discussed.

This local committee is then given the responsibility of selecting the place for the meeting, supplying ushers, and taking care of all publicity except radio announcements, which are made over the area through the radio program facilities of the state department of health. The committee is encouraged to realize it is up to them to secure a large attendance for both the afternoon and evening sessions.

The program usually is presented in two parts, at 2:30 p.m. and again at 8:15 p.m., three half-hour talks being presented at each session. After each half-hour presentation there is opportunity for questions to be asked by members of the audience. The chairman is instructed about his duty to see that these question periods are conducted properly and that so-called "crackpots" are not permitted to carry the discussion too far from the subject at hand. The sessions usually last about two hours in the afternoon and two hours in the evening. Our afternoon audiences have been much smaller, and experience has proved that it is possible to get more interest, particularly in the questions, during the evening session.

In our experience we have found it better to have just an evening program with three half-hour talks, if the local committee so elects, because the afternoon meetings are, as a rule, poorly attended. Some communities definitely want an afternoon session for the women who cannot come out in the evening, and when this is the case, we try to furnish subjects that will appeal to women.

In some instances high school seniors have shown a desire to attend the afternoon sessions, and for these communities, speakers are chosen who would be most likely to carry an appeal to both high school seniors and adults.

A special point is made of encouraging speakers who take part in the forums to use lay language which can be understood by the entire audience. After the local committee selects the subjects from the list of topics available, the state society of the profession submitting the selected topic is notified by the director and requested to name a speaker, preferably from the area where the forum is to be held. For example, if the topic is rheumatic fever, the state medical society is notified and asked to designate a suitable physician to discuss the disease. The director then contacts the doctor and supplies him with all the details for his appearance, the date and place of the meeting, and such other information as may be necessary for the occasion. Insofar as possible we try to schedule addresses by medical men in the evening so as not to take them away from their practices during the day.

Every effort is made to enlist the co-operation of local lay individuals. The plan is to let them "carry the ball" in this effort to bring health education to the citizens of the community. We do not believe it wise to let the lay individuals feel that the medical society or its allied professions are attempting to impose the program upon the public. If the local group wants to take the lead and will do the proper advertising and lay the proper groundwork, we will furnish the program.

In this respect we have two philosophies: In our original plan, we attempted to get the presidents of every organization in the community to attend, with their secretaries, or send representatives to an over-all planning meeting at some date well ahead of the proposed forum. In some of the communities we have found that this leads to divided responsibility, and unless you can get an enthusiastic "spark plug" in the community, the possibility of "everybody's business being nobody's business" will contribute to a lack of organization and planning or a small audience. For this reason, sometimes it is better to secure a large, enthusiastic, responsible organization in the locality to take the lead. If, for instance, we select an enthusiastic city Parent-Teacher Association Council, made up of a large number of local parent-teacher groups, to sponsor the meeting, it is better than to attempt to secure a number of different organizations for the same purpose. The choice of procedure, however, should be based largely upon what is learned about the community before the anticipated forum is scheduled.

In the State of Iowa, as well as a good many other states, there is a definite movement for the organization of health councils which would abbreviate a lot of the work needed to organize a

forum every year. These health councils should definitely have the support, interest and cooperation of the various organizations that are members of the Interprofessional Association, for they need the guidance of the trained workers in medical and associated professions, without which they cannot accomplish their purpose with any degree of efficiency. Therefore, on the back of each program given out at the health education forums we urge the community to consider the possibility of organizing a health council as the best means of bringing together all the health workers in the community.

If the chairmen of the various committees in the community are brought together to discuss health problems, there is a future possibility that they can very well form the nucleus of a health council. However, it is highly important that representatives of all the organizations in the Interprofessional Association, who live in that area, become a part of the health council and lend their support and interest through personal attendance. This presents a problem within our own organization, which will require a lot of effort on our part to get our members to realize and act on this responsibility in the plan. It would not seem advisable, however, that these men take the complete lead, as this might be misunderstood. But it certainly is highly desirable for them to sit in on the plans and become a part of the community or county health council.

We would like to point out that at each and every one of these forums the director should specifically make the statement that all the organizations in the Interprofessional Association and the state department of health are tremendously interested in community welfare, community health and community betterment; and that these organizations are presenting this health education forum because of their interest in the community. The audience is informed that the local members of the various organizations in the Interprofessional Association are happy to work with the community groups for health improvement through techniques adopted by the health council, and that they are desirous of being called upon to sit in on meetings and given opportunity to be of assistance.

It should be pointed out that there is no expense to the local community for any of the services. The organization and contact work is done by the director of public health education of the Iowa State Department of Health. Expenses of the speakers from the Interprofessional Association are borne by their respective organizations, and, likewise, speakers and the director from the health department are paid for by their own agency.

COMPLEX SIMPLE FRACTURE

To the Editor:—Realizing that the term "simple fracture" as generally defined is thoroughly inadequate to describe the trauma received in many so-called simple fractures, I have added a new definition to the simple and compound fracture nomenclature, i. e., "complex simple fracture" (Key, J. A., and Conwell, H. E.: The Management of Fractures, Dislocations and Sprains, ed. 4, St. Louis, C. V. Mosby Company, 1946, pp. 41-43).

A complex simple fracture is a fracture which is not compound but which has received severe trauma to either or all of the surrounding soft structures, i. e., skin, muscles, blood vessels and nerves. The bony fragments usually are displaced to a marked degree.

"Complex," as defined by "Webster's New International Dictionary," unabridged, is as follows: (1) an assemblage of related things; (2) a whole made up of complicated or interrelated parts.

The complex simple fracture should be further described as to the type of bony injury, for example: complex simple fracture (transverse, comminuted, spiral or oblique, as the case may be).

Through personal contacts and correspondence with the personnel of the three National Fracture Committees (American Medical Association, American College of Surgeons and American Academy of Orthopaedic Surgeons) with reference to their opinions and the necessity for such new fracture term or definition, there was unanimous agreement that such a definition of complex simple fracture was a necessary one and should be generally accepted and used in its broad meaning.

I make an appeal that this new fracture definition or its relative equivalent be used by the members of the medical profession. Besides expressing more adequately the pathologic process in such type fracture it will mean improved records for the hospitals and convey a better description of the fracture to the insurance companies, compensation boards and other related agencies, thereby being of much help to the patient, the physician and every one concerned.

I will appreciate any opinion or suggestions relative to the foregoing.—H. Earle Conwell, M.D., Birmingham, Ala.

Reprinted from the Correspondence Department of The Journal of the American Medical Association, October 25, 1947, Vol. 135, p. 531

MEDICAL ORGANIZATION AND SOCIAL PROGRESS

WILLIAM D. STOVALL, M.D.

Madison, Wisconsin

IT is unusual for the president of a state medical association, particularly a new president—I became president in October—to suggest or even intimate or insinuate that administrative organizations of the society should be modified. To be asked—indeed, to be invited—to discuss such changes is exceptional. I suspect that there may have been some element of humor at my expense in scheduling me as a streamliner of the organization. However, I might say that I, too, can enjoy the sport of it, and it was more in the spirit of challenging you and of getting your reactions to the opinions of a fledgling that I agreed to talk on this subject. Without this spirit of comradery, I believe I would be frightened at the task which the subject sets for me. So, with somewhat of a sense of humor at my predicament, I have the temerity to make some comments on reorganizational changes for state medical associations.

You will understand that my remarks are predicated upon Wisconsin experience only and therefore may not be at all applicable in other states. And, also, it must be said at the outset that the idea that some helpful change might be devised in the methods by which doctors approach the many and important problems which confront them has been considered for some years past by many of us, and, also, that the suggestions here made are not altogether my own. All that I say is compounded from contributions made by the councilors, the secretary, Dr. Dawson, our president last year, and many others.

From my own observations I should like to point out a few of the things that to me would contribute a better understanding of what the problems of medicine are. It has seemed apparent to me that the committee structure of our association has grown up like Topsy, or possibly I should say like various committees, boards, and commissions that have been added to the various divisions of our government at all levels—county, state, and national. This has occurred as the result of colliding with all sorts and kinds of economic and social problems, creating intraprofessional, interprofessional and nonprofessional differences of opinion and strife. These collisions have usually been sudden, that is, unexpected, and the immediate effect is the organization of another committee to solve a problem that no one knows very much about and which has taken everyone by surprise. After the committee or council, or whatever the designation, has once been created, it stays on forever and continues on the records as an active committee whether or not it is active. And sometimes, it seems to me, they meet and report whether or not they have made any special study or investigation of the subject with which they are concerned. In this way the committee structure piles up year after year until the system becomes an octopus of committees, many of which do not formulate their opinions from expert knowledge.

It is further my opinion that this has occurred because of two things: first, our failure to anticipate what the future may hold for us, and therefore our failure to plan to meet the oncoming situation; second, the preoccupation of physicians with their own affairs, until they are detracted and then distracted by the reverberations of public conflict over affairs in which they suddenly find that they have a vital interest, not only from a professional point of view but from the point of view of a citizen.

A good historical background and acquaintance with current advancing knowledge supply the material for the construction of watchtowers from which future events can be visualized, and form the ingredient with which wise plans to meet these events can be constructed. Much of the discordance, discontent, disturbance, and disagreement in the profession could have been avoided or greatly modified by wise planning from a knowledge of the historical background.

We are not in our present upheaval by accident. Great trends in human affairs grow out of the past like a tree grows out of the soil. The science of disease control and prevention has moved in one direction, from environmental sanitation to the treatment of the individual—even "he that runs may read."

Read at the North Central Medical Conference, November 23, 1947, Saint Paul, Minnesota.

Dr. Stovall is president of the Wisconsin State Medical Association.

All affairs—governmental, private, or voluntary—that are operated by democratic methods are congenitally slow moving and react ponderously to change and have the reputation of being cumbersome and ineffective. I have no doubt that these qualifications prompted the statement, "Free government is better than good government." All of us agree to the sense of this statement, but certainly we cannot agree with all of its implications. Free government is certainly far better than good government if good government means the loss of freedom. However, the implication that free government cannot be good government, we cannot and do not readily agree to. Since our societies are democratic organizations, they do have some of the genetic defects of any such system.

Colliding with complex problems instead of planning to prevent them is, no doubt, one manifestation of the awkwardness of free and democratic institutions. But is it not possible to improve this awkwardness without losing the freedom we want within the organization? Do we admit that free and democratic institutions cannot be improved to meet a changing world? I for one think that improvement can be effected by effort and interest, and that free and democratic organization can be made to operate in a superior and a superlative manner. In my opinion this is essential to the preservation of free institutions and to the preservation of the dignity of the individual.

Preoccupation with professional concerns is a great obstacle for physicians in devising an organization to meet present-day needs. Physicians have enough to absorb their time and attention. It is easily understandable that they shun and shy away from participation in outside activities. Their preoccupation with medicine interferes with obtaining a familiarity with problems of public concern and other matters which so profoundly influence methods by which a complex system is organized, and which determine the problems which such organizations bring to the profession. It is necessary, however, if physicians are going to prevent collision with ideologies that are inimical to good medical practice, that they become informed about the concepts upon which these ideologies are grounded and with the technical practices to which they eventually lead.

In brief, these are some of the considerations which encouraged me to suggest some changes in the medical organization of our state to meet certain economic and social problems resulting from increased medical knowledge. After a review and consideration of some of our immediate problems, it seems to me that they call for only a few very well defined activities, each one, of course, being composed of a great many details which require careful study before their significance can be wisely incorporated into our way of life. These activities might be carried out under the following headings:

1. Medical education and hospitals.
2. Scientific work and postgraduate study.
3. Budget and finance.
4. Public health and governmental activity.
5. Economics, medical service, and public relations.

If one follows the proceedings of the House of Delegates year after year, it will be seen that these five subjects cover quite completely the problems that are brought to that body. And if one has followed these proceedings, it must be apparent that many resolutions come before the House which bear on matters, the historical background and current developments of which have not been given studious consideration. As an illustration we can use medical education. At the present time there are conflicting ideas on what can be done to encourage young physicians to choose the general practice of medicine instead of some special field of practice. A committee of the state medical association should be appointed to study this problem and bring back to the councils of the society definite recommendations, after careful study of the historical development of medical education in this country and the factors which are influencing present trends. It has been said that the tide cannot be swept back; this we believe, but if we are prepared we can ride the tide out and enjoy the ride. There isn't time for me to carry these illustrations further. There isn't time for me to discuss each one of the items that I have suggested as suitable for committee or council work, but I would like to say what we have done in Wisconsin.

At the last meeting of the House of Delegates I asked for authority to appoint a committee to study the committee structure of our state medical association, and to report back to the House of Delegates the results of their findings. I feel that we need a very strong and active committee structure, because I have seen how excellently

the various councils of the American Medical Association work and because the Council on Scientific Work of our own medical association has so successfully handled the scientific affairs of our society. I have been encouraged to believe that, in our organization, five councils of fifteen members each, each member to serve a period of five years, with a chairman to be appointed by the incoming president, would provide a mechanism for definite study and deliberation on these problems, whereby knowledge and advice would form a basis for critical action by the House of Delegates. This does not mean that the incoming president would change the chairmanship, but he could. The chairmen of these five councils would act as a cabinet for the president. It might be said that the committees are too large. The thought is that each council may divide itself up into subcommittees, assigning various problems to small groups. This seems advisable because each member of a committee cannot, in the time at his disposal, familiarize himself well enough with all the subjects which would come before the council to provide an expert opinion.

By a division into smaller groups it is possible, however, for the individual groups to become well versed in restricted fields of knowledge. Since it has become popular to be critical of continuous service over a long period of time, it may be said that the period of service of each committee member is too long and that the restriction of the number of councils or committees reduces active participation in medical society affairs to a small group. The size of these committees precludes that, and the appointment of new members each year to take the place of those whose terms expire would be drawing new personnel into the committees. They would pass out into the ranks of the membership to become leaders. This process in a few years should build a strong society of critically and constructively thoughtful members.

I am so convinced that the maintenance of a free government depends upon a strong local leadership that I think one of the chief functions of a state medical association is to develop leadership among its members. This can be done only by giving them responsibility and allowing them to become informed in certain subjects. In this way alone will the profession be able to influence public opinion, after careful deliberation on well-considered subject matter rather than by whim or fancy. Curti, in his book, *The Growth of American Thought,* refers to Beard's plea that those concerned with human affairs distinguish between what is known and can be proved and that which is longed for and loved. We in the medical societies must also realize this, and have opinions of our own that are based upon the facts as they are, or at least the facts as we can obtain them, and boldly deny the flattery of the uninformed and those who thus plan the failure of plans of people living under a government of free people. In this way we can maintain free institutions and free people, and have good medical practice and good government as well.

EXAMINATION FOR REGULAR CORPS, USPHS

A competitive examination for appointment in the Regular Corps of the United States Public Health Service in the grade of assistant surgeon (first lieutenant) and senior assistant surgeon (captain) will be held in October. The written examination will be conducted October 4, 5, and 6 at places convenient to the candidates. The oral examination will be held at various points throughout the country.

All applicants must be at least twenty-one years of age and citizens of the United States, must present a diploma of graduation from a recognized medical school and satisfactorily pass a physical examination performed by Public Health Service officers.

Physicians beginning internship on July 1, 1948, will be admitted to the examination. Successful candidates will be placed on active duty in the Regular Corps upon completion of internship on July 1, 1949.

Applicants for the grade of assistant surgeon must have had at least seven years of educational and professional training or experience, exclusive of high school. Applicants for the grade of senior assistant surgeon must have had at least ten years of educational and professional training or experience, exclusive of high school.

Entrance pay for an assistant surgeon with dependents is $5,011 a year and for senior assistant surgeon with dependents $5,551 a year. This includes the additional pay of $1,200 for medical officers, as well as subsistence and rental allowance. Provisions are made for promotions at regular intervals up to and including the grade of senior surgeon (lieutenant colonel) and for selection for promotion to grade of medical director (colonel) at $9,751 a year. Retirement is authorized at either completion of thirty years' service or at the age of sixty-four. Full medical care including disability retirement at three-fourths pay is provided.

Application forms may be obtained from Public Health Service Hospitals, District Offices, or by writing to the Surgeon General, United States Public Health Service, Washington 25, D. C.

A REVIEW OF THE EPIDEMIOLOGY OF SCARLET FEVER

ALEX G. BERGER, M.D.

Acting Director, Acute Communicable Disease Control
Health Department

Minneapolis, Minnesota

IN 1924, when the Dicks reported their experimental production of scarlet fever by swabbing the throats of several human volunteers with a strain of hemolytic streptococcus isolated from a previous case of this disease, the scientific world had in general accepted such experimental findings as conclusive proof of the specific etiology of scarlet fever. However, since that time, new laboratory methods of differentiation between the various hemolytic streptococci have led to the discovery of so many significant additions to the epidemiology of scarlet fever that an entirely new concept of this disease has resulted. The writer therefore feels that a brief review of such developments, presented in the order of their occurrence, may provide a more unified and complete concept of scarlet fever as it is understood today, and be of help in clarifying the new epidemiological approach deemed necessary for its control.

Although fairly accurate descriptions of scarlet fever appear in the literature as early as the middle of the sixteenth century, it was Sydenham who first employed the term "scarlet fever," and carefully described the disease as it appeared in London from 1661-1675.[6] Thereafter, scarlet fever became more and more clearly defined as a clinical entity. However, it was frequently confused with diseases such as diphtheria, measles, and various other rash-producing infections. Such difficulty in its diagnosis lent emphasis to the desirability of a laboratory aid for its differentiation, and therefore served as an added stimulus in the search for its etiology. Still, for a long time, attempts at identification of such causative organism proved difficult and baffling.

Early ideas relative to the etiology of scarlet fever included protozoan, bacterial, and virus concepts. It was Mallory in 1904 and Dohle in 1912 who made the suggestion that scarlet fever was due to a protozoan infection, inasmuch as inclusion bodies were frequently found in the tissue cells of scarlet fever patients. However, similiar inclusion bodies were later found in other infections, so this idea was soon discarded.[6]

The possibility of a streptococcus as the etiological agent of scarlet fever was suggested as early as 1885 by Crook, who reported the presence of streptococci in the blood and organs of individuals dying of this disease. About this time also, Klein had succeeded in isolating a streptococcus from the tissues of scarlet fever patients and named it Streptococcus scarlatina. In 1900, Boginsky and Sommerfeld reported the constant finding of streptococci in the throats during the characteristic angina of seven hundred individuals suffering from scarlet fever. Streptococci were also frequently noted accompanying the various septic complications occurring in this disease.[6]

"Such association of the hemolytic streptococcus with scarlet fever led some investigators to propose the view that the streptococcus is the etiological agent of scarlet fever."[6] Others, however, considered such possibility as quite unlikely inasmuch as the reactions to these infections were quite dissimilar. One attack of scarlet fever seemed to confer life-long immunity, yet streptococcal infections could recur in the same individual time and time again. They therefore felt that the causative organism of scarlet fever was probably a virus, and that the streptococcus plays the role of secondary invader.

Such differences in streptococcal reaction might have been more easily understood if the heterogeneity and complexity of the streptococcal group had been more fully appreciated at that time. Though differences in the behavior of these organisms had been noted from time to time, it was not until 1918 that laboratory proof of the existence of different streptococcal strains was made available. At this time, by means of agglutination and protection tests, Dochez, Avery, and Lancefield clearly demonstrated the existence of at least four different serological types.[7]

Thus far, therefore, evidence had been advanced to show that not only were hemolytic streptococci closely associated with scarlet fever and its complications, but they were also heterogeneous in character and consisted of separate and distinctly different strains. Such evidence could easily account for both the different types of infection produced and the variability in immunity

formation. Scarlet fever, it was suggested, could very well be just one of the various streptococcal infections caused by a specific strain of hemolytic streptococcus. To definitely prove such a possibility, it was necessary to reproduce the disease through the experimental inoculation of such organism into another animal, preferably a human being.

Probably one of the earliest attempts at such a procedure consisted of the experimental production of scarlet fever in swine by Class in 1899, through the inoculation of a coccus-like organism. This organism may well have been a hemolytic streptococcus for it had been isolated by him from 300 cases of human scarlet fever.[6]

Later, in 1914, Krumwiede, Nicoll, and Pratt reported the scarlet fever infection of a laboratory worker which followed her accidental swallowing of living streptococci, containing streptococcus scarlatina. Efforts at this time to infect monkeys with the same streptococcus were unsuccessful.[6]

Still later, in the year 1921, attempts were made by Dick and Dick to reproduce scarlet fever by the experimental inoculation of human volunteers. Their efforts were unsuccessful at this time. However, in 1923, Dick and Dick, using hemolytic streptococci cultured from the infected finger of a nurse suffering from scarlet fever, successfully reproduced scarlet fever in a human volunteer by swabbing these organisms on the pharynx and tonsils. Furthermore, to assure themselves that the causative organism was the streptococcus and not a virus associated with such streptococcus, they cultured this organism in bottles of sheeps blood agar, and passed the condensation fluid through a Berkefeld V. filter. Inoculation of the filtrate did not produce scarlet fever, yet later inoculations of the unfiltered culture in the same individuals occasioned another case of scarlet fever. Such experimental evidence, the Dicks believed, satisfied all of Koch's postulates, and therefore definitely established the etiology of scarlet fever.[4]

In addition to the findings relative to its etiology, other important features of scarlet fever had been concurrently noted by various investigators. For a long time, students of scarlet fever had been impressed with the similarity of this disease to diphtheria. Thus, Berge in 1895, suggested that just as in diphtheria, so also in scarlet fever, the symptoms were due to the absorption of soluble toxins. In 1907, Gabrichewsky attributed the scarlatiniform reactions, which occured during his attempts at scarlet fever immunization, to a toxin present in the vaccine. Later, in 1918, Schultz and Charlton revealed the presence of scarlet fever antitoxin in the serum of normal adults when they demonstrated the blanching or neutralizing effect that such serum had on the rash of scarlet fever. They found the serum of about 60 per cent of normal adults to possess this blanching reaction. In 1923, Mair pointed out the significant fact that the blanching power of the serum of a child was negative if tested before an attack of scarlet fever, but became positive after such infection. Furthermore, on comparing groups of adults and children who had not had scarlet fever, he found that the sera of the adults possessed this blanching power much more often than did the sera of the children.[6] Such a finding indicated that adults may develop scarlet fever antitoxin through subclinical exposures to the organism without necessarily developing the disease. Finally in 1924, the Dicks made practical application of the above findings, and introduced the now very well known Dick test. They found that by injecting, intracutaneously, small amounts of a filtrate containing scarlet fever toxin, they were able to detect the presence or absence of scarlet fever antitoxin. Children who gave no history of scarlet fever, i.e., who possessed no antitoxin, reacted in a positive way to such infection by developing an erythematous area at the point of injection. The same test when performed on children after they had recovered from an attack of scarlet fever produced no erythematous area, i.e., gave a negative reaction. Thus a test had been provided whereby susceptibility to the scarlet fever toxin, and presumably to scarlet fever infection, could be ascertained.[5]

At this stage, therefore, it seemed that the epidemiology of scarlet fever had been practically completed. The long confused and controversial concept as to its etiology had apparently been definitely clarified. A test had been devised whereby evidence of susceptibility as well as immunity to scarlet fever infection could now be ascertained. The value of scarlet fever antitoxin and convalescent serum had already been demonstrated. By this time also, the Dicks had suggested the inoculation of graduated increasing doses of scarlet fever toxin as a method for the active immunization of susceptible individuals. Truly then, it appeared that the mysteries of scarlet fever had

been cleared, and the means for its eradication had been provided.

Careful observations, however, by students of this disease, soon revealed various discrepancies and perplexities which could not be adequately explained by the epidemiology of scarlet fever thus far elaborated. It did not explain why individuals who were Dick-negative would, after exposure to a scarlet fever case, not infrequently exhibit symptoms similar to scarlet fever in practically every detail, except that no rash would appear. Such reactions appeared to occur most often in the adult contacts of a definite scarlet fever case. Occasionally however, the reverse would occur, and the first indication of an infection in the family would be a sore throat in one of the adults, following which one or more of the children would come down with typical scarlet fever.

Confusion also presented itself in the consideration of milk-borne epidemics of sore throat. Since 1900, epidemics of septic sore throat had been considered by the majority of physicians as comprising a clinical entity. Davis, in 1929, reiterated his claim that the streptococcus isolated by him in 1912, from a milk-borne epidemic of sore throat, was a distinct species. This organism, which he called *Streptococcus epidemicus,* he believed was the sole cause of this disease. On the other hand, Smillie had observed in 1917 that in many septic sore throat epidemics, scarlet fever cases also occurred, and that both types of cases might be traced either to cases of scarlet fever or to septic sore throat. Outbreaks of septic sore throat, therefore, had, from time to time, been reported as giving a varying clinical picture; and scarlet fever, as well as erysipelas and other septic conditions, had been observed in the same epidemic.[13]

Further perplexities in the understanding of scarlet fever, which could not be explained at this time, arose from the fact that the clinical picture of this disease seemed to vary considerably on different occasions. Typically, the clinical picture of scarlet fever, consisting of a sore throat, high fever, nausea, vomiting, and a fine punctate rash, which was later followed by desquamation, was unmistakable and easily diagnosed. However, every now and then, cases would occur so mild and atypical in character that diagnosis at times would be almost impossible. Such cases might display only a very mild fever, little or no sore throat, and an almost negligible rash which might last only for hours instead of the usual three to seven days.

Clarification of such problems and confusing situations, was made possible only by the development of more specific laboratory methods for the differentiation and detailed classification of the hemolytic streptococci.

Though attempts at streptococcal classification had been made by a variable number of bacteriologists, the methods as suggested by Lancefield and Griffith seem to have been found most reliable, and have therefore been most widely accepted. It had long been known that the hemolytic streptococcus did not confine itself to the invasion of man alone. Attempts, however, to differentiate the streptococci, in accordance with their sources and their variable pathogenicity, had not heretofore been too successful. Fairly adequate methods for distinguishing the human from the nonhuman streptococcal pathogens had been attained by the use of various biochemical and cultural reactions. Such methods were, however, neither complete nor as specific as might be desired. It was not until 1933 that a new and specific method for such differentiation was made possible. At that time, Lancefield came forth with a precipitin reaction by which she was able to divide the hemolytic streptococci into several distinct groups.

"The precipitin test," she stated, " is dependent on the presence in streptococci of substances characteristic of the large groups, although not specific for the types within the groups."[15] By precipitating or extracting such substances from the bacterial cell, she was better able to reveal the serological differences that existed between the various groups of streptococci. Thus, hemolytic streptococci of human origin were found to contain a carbohydrate called "C" substance, which is not type specific and yet is not found in strains from sources other than man. Further experimentation revealed that similar carbohydrate substances were also to be found in the other streptococcal groups. These substances, although chemically related to the "C" substance of the human group, were serologically different and therefore specific only for its own particular group. On the basis of such serological differentiation, the hemolytic streptococci were at first divided into five groups, and at present are divided into at least nine different groups. They are listed as A, B, C, D, E, F, G, H, and K.

Group A was found to comprise strains chiefly of human origin, and with few exceptions, contained all of the human pathogenic strains.[15]

Attention has therefore been centered primarily on this group, and methods for its further division into its component strains or types have been carefully studied. Here again, Lancefield pioneered, for in 1919, together with Dochez and Avery, she had initiated the first systemic classification of hemolytic streptococci of human origin.[7] Later, in 1928, she demonstrated the presence of a type-specific substance of protein character in the hemolytic streptococcus which she called "M" substance, and by a precipitin technique separated a number of immunologically distinct types.[16] About this time also, another improved method for the differentiation of the human streptococcal pathogens was developed by Griffith. This method consisted of slide agglutinations of the various hemolytic streptococcal pathogens with absorbed antisera, i.e., before agglutination with the unknown organism is attempted, each antiserum used is absorbed with a suspension of organisms made up from all of the heterologous types. By such method, Griffith was able at that time to distinguish more than twenty serological types of hemolytic streptococci.[12] At present, with the aid of both the Lancefield and Griffith methods, the hemolytic streptococci of group A have been divided into at least forty different types, numbered as types 1, 2, 3, 4, et cetra.

Introduction of such improved laboratory methods to the scientific world led to new attempts at the isolation and specific identification of the organisms present in the various streptococcal infections. Consequently, a vast amount of new facts has been gathered—facts so radically different from previous impressions that an entirely new concept of scarlet fever and its associated streptococcal infections has resulted.

Cultures of scarlet fever patients, when examined by these new methods, uncovered data that definitely proved the belief of the Dicks and others, relative to the specific etiology of scarlet fever, to be erroneous. Thus, as early as 1927, Griffith, on identifying the organisms of 60 per cent of the scarlet fever cases occurring in Great Britain, was able to show that at least four different types were involved.[9] Reports from investigators in other countries soon revealed that still other types were to be found in this disease. In fact, Schwentker has recently noted that all known types of group A have at one time or another been recovered from Scarlet Fever cases.[22] Generally, however, it was found that during epidemics, only a few streptococcal types tend to predominate, but that these types differ from place to place and from season to season.[9]

Likewise, investigators now dispelled the belief that other hemolytic streptococcal infections, such as septic sore throat, erysipelas, or puerperal sepsis, were specific in their etiology. It was now found that the same organism which would cause scarlet fever in some individuals might produce a septic sore throat in others, while still in others it might occasion erysipelas or puerperal infection. Careful studies indicated that just what happened when hemolytic streptococci attacked an individual was determined by at least three factors: (1) the resistance of the host, (2) the site of the implantation, (3) and the characteristic properties of that particular hemolytic streptococcus. An analysis of each of these factors should therefore be considered at this time, if their manner of operation and resultant effect are to be clearly understood.

A study of the hemolytic streptococci has shown that their pathogenicity is dependent not only upon their ability to produce erythrogenic toxin but also upon their ability to invade tissues. A detailed study of the invasive properties of these organisms indicate that such abilities are occasioned by the capacity of the streptococci to synthesize and elaborate a number of substances that react with human tissues. Some of these substances and their effects have been identified. They include two streptolysins which lyse human erythrocytes (one of these is oxygen labile, while the other is oxygen stable): fibrinolysin which dissolves human fibrin; and hyaluronic acid, a component of the capsule of the bacterial cell, which facilitates the spreading of the streptococcus throughout the tissues.[2]

The pathogenic properties of the hemolytic streptococci have been found to vary considerably, both in quality and quantity. Thus, while some organisms might be especially invasive in character, such organisms might have little or no ability to produce erythrogenic toxins. On the other hand, the reverse might also be true, and organisms which have high toxin-producing ability might possess invasive qualities of little or no consequence. All possible combinations of the above properties were found to exist, and as such, tended to determine the type of streptococcal

infection occasioned. Thus, Evans in a recent review noted that types 3, 8, and 10 appear to be high in their toxin-producing qualities, for they were almost constantly associated with scarlet fever but rarely with any other streptococcus infections. On the other hand, types 5, 13, 14, and 18 appear to have low toxin-producing ability but high invasive qualities, for they were rarely associated with a rash, yet commonly produced suppurative and other miscellaneous streptococcal diseases. Types 6 and 19 were found to be associated with suppurative diseases on some occasions and with scarlet fever infections at other times. Such a combination of effects could, therefore, indicate that they possess both toxin-producing action and a high invasive ability.[8]

The type of infection produced, however, is dependent not only on the invading pathogen but also upon the resistance of the host involved. The Dicks had previously noted that individuals who were susceptible to the erythrogenic toxins, i.e., Dick-positive, reacted to the hemolytic streptococcus by developing typical scarlet fever, while others who had become Dick-negative would not develop the disease. More recent studies, however, demonstrated the fact that, though immune to the rash-producing toxin, such individuals may still be subjected to all the signs and symptoms occasioned by the invasive features of such organism. A Dick-negative individual might therefore display the symptoms of a septic sore throat if the invading organism attacked the nose and throat; erysipelas if such organism invaded the skin; or puerperal sepsis if the uterine tissues were attacked.

Consideration of scarlet fever, in the light of such new experimental data, has therefore resulted in an entirely new understanding of the disease. What had long been considered a specific infectious disease now appeared to be a disease syndrome caused by any one of a wide variety of hemolytic streptococci.[9] Such syndrome, it was found, represented the composite effect of two components, namely, an infective or invasive component and a toxic component. The infective component is responsible for all signs and symptoms resulting from the invasion of tissue. These symptoms are similar in all streptococcal infections, whether such infection be scarlet fever, erysipelas, puerperal fever, or simple angina. It is this component that is the cause of any extension of the infection to adjoining structures, and is therefore the element responsible for most of the complications occurring in scarlet fever. The toxic component, on the other hand, is related chiefly to the systemic effects, and is therefore responsible for the exanthem and enanthem, and for the reactions of vomiting, arthralgia, and albuminuria.

When scarlet fever is produced, its clinical form will depend largely on the relative proportion of the toxin-producing and invasive qualities present in the causative organism. Thus, as emphasized by Gordon, one clinical type may exist in which the manifestations are essentially toxic, still another in which the invasive qualities predominate, while a third may represent a mixture of the above two elements. The mixed form is the type usually responsible for the manifestations of typical scarlet fever, and is variously designated as light, moderate, or moderately severe. "Aside from this group of readily recognized reactions, there is a group of atypical infections of varying extent, mild in nature, and difficult to diagnose. They represent essentially low-grade invasive reactions, with the toxic element indefinite and sometimes so slight that the eruption of the skin is most fleeting."[9]

In addition to the above clinical manifestations of scarlet fever, Gordon has drawn attention to still another form of infection which is latent or subclinical. Here, "The toxic element is absent, and the invasive factor so slightly active that it leads to no clinically recognizable sign. There is clear cut evidence of the existence of this group, but little appreciation of the number of cases involved in proportion to the other two."[9]

Control

Although the present incidence of scarlet fever appears to be as great as ever, the general level of severity in this infection seems to have progressively decreased. Pope, in a review of the experience of Providence, Rhode Island, for the years 1865-1924, reports that whereas in 1886 there was one death in every five cases of scarlet fever, there was only one death in every 114 cases in 1923.[9] Woods, in 1933, showed that a similar change had occurred in England and Wales. Examination of scarlet fever fatality rates in Minnesota likewise reveals a progressive drop from a high of 6.9 per cent in 1910, to a low of .2 per cent in 1946. In most parts of the world, therefore, scarlet fever is today a mild disease,

with deaths less than 4 per cent of what they were eighty years ago.

Has scarlet fever, then, at last been subdued? Can it be that the general betterment of our health conditions, and the better medical care now available, have together been instrumental in permanently changing a fearful and highly fatal disease into a relatively mild and innocuous ailment? Possibly. Yet it is well to note that throughout the generations, scarlet fever has frequently exhibited extreme variations in its severity. Thus in the middle of the seventeenth century, Sydenham described scarlet fever as extremely mild. Toward the end of the eighteenth century, scarlet fever was again severe. Immediately after this period, the severity diminished, and from 1804 to 1816, it is again alluded to as a mild disease. However, after 1830, the disease is noted by Creighton as "the leading cause of death among the infectious diseases of childhood." Such severity apparently remained until the middle of the nineteenth century, when the present progressively downward trend began.[9]

It would be difficult to foretell just how long scarlet fever will remain a mild disease. Even during this generally mild period, scarlet fever, as well as all other streptococcal infections, has on certain occasions temporarily reverted to a form exhibiting a marked increase in severity. Coburn has shown that, both in World War I and II, a combination of factors such as a large number of susceptible recruits, a general disturbance in the living conditions of the host, and the spread of virus infections, would occasion a sudden increase in the pathogenicity of the streptococcus and thus produce intense cases of scarlet fever and other streptococcal infections.[2] It would be much wiser, therefore, to guard against the consequences of any future change in scarlet fever severity by promoting and establishing more adequate methods for its prevention and control.

The control of scarlet fever does not lie in measures directed only at the typical scarlet fever case, for, as has been shown, this group constitutes only a small fraction of all the various clinical forms of this disease. Adequate control measures should encompass all forms of scarlet fever infection and should therefore include the atypical case, the subclinical case, and even the normal carrier of the scarlet fever organism. Moreover, since all types of hemolytic streptococci have, at one time or another, produced scarlet fever,[22] and since these same streptococci may have at one time, occasioned scarlet fever and at another time produced erysipelas, streptococcal sore throat, or any other streptococcal infection, a program of prevention and control should deal with this whole group of streptococcal infections and not simply with those which show a rash.

Measures for the control of streptococcal infection must concern themselves with the factors that determine the communicability of a disease. Such factors include a reservoir of infection, a means of transmission, and a group of susceptible individuals. Eradication of even one of these elements could break the chain of communication, and thus eventually eliminate such infection. Such a procedure, however, is rarely possible. More feasible, therefore, would be a setting up of measures for the limitation and modification of these factors. If successful, such a procedure could result in a significant reduction in the incidence and severity of streptococcal disease.

Reservoir

Although the hemolytic streptococcus is capable of producing a great variety of diseases in man, scarlet fever seems to be the only one of such infections where control measures have been attempted. For generations it has been recognized that scarlet fever is a contagious disease, that its reservoir is man himself, and that its mode of transmission is primarily through human contacts. Accordingly, rigid measures were set up for the isolation of the patient and the quarantine of his immediate contacts. Such measures have usually created much inconvenience and economic distress. Consequently, many infractions of the quarantine regulations have resulted, and not infrequently attempts have been made to avoid the reporting of such cases to the health authorities. Gordon has recently estimated that less than 70 per cent of the recognizable cases of scarlet fever are registered with the health authorities.[10]

In addition to this number of unreported typical cases, we find that there are many atypical scarlet fever cases, streptococcal carriers, and numerous hemolytic streptococcal infections other than scarlet fever, that rarely, if ever, are subjected to any control measures. We can thus appreciate how small a fraction of the total load of streptococcal infections is really affected by our present health regulations.

If our measures for control are to be at all adequate, health regulations must be changed to include all streptococcal infections. Such a change necessitates the close co-operation of physician and patient with the official health agencies. This means a prompt and complete reporting of cases and suspects by the physician, and a conscientious observance of the prescribed regulations by the patient. Such co-operation can usually be attained only if the inconvenience to the patient is reduced to a minimum.

Recognizing these facts, public health authorities are making attempts to liberalize their regulations and are recommending radical changes in the period of isolation for scarlet fever cases and in the quarantine restrictions for their contacts. Thus, in 1945, the American Public Health Association in their booklet, *The Control of Communicable Disease,* came out with the suggestion that scarlet fever be considered in the same category as all other hemolytic streptococcal infections due to Lancefield's group A, and that the isolation period of this whole group of streptococcal infections be limited to fourteen days in uncomplicated cases. They further suggested that the quarantine of contacts is not indicated and that the placarding of the home may be omitted.[1] New York City has gone even further, and since 1945 has reduced its isolation period for all uncomplicated hemolytic streptococcal infections, including scarlet fever, to "not less than seven days." They also do not restrict their contacts, and allow children contacts to attend school during the isolation period of the patient.[18]

Changes such as these are not without criticism. It is not uncommon for a physician to be called upon to treat children with scarlet fever who are apparently infectious much longer than seven days, some even as long as four weeks. Some physicians, therefore, feel that a radical reduction in the period of isolation might be the source of an increase rather than a decrease in secondary infections. Thus far, however, New York City has not found this to be true, for the number of cases of scarlet fever reported previous to the setting up of this new regulation compares very closely with the number of cases reported in the past two years.[18] It is well also to note that this marked reduction in isolation period refers only to simple cases, i.e., without complications. If complications are present, such regulations require the continuation of isolation until such complication either has disappeared or has been definitely proven to be noncommunicable. This is in accordance with Gordon's observation in 1932, when he definitely showed that it is the complicated case rather than the simple which is primarily productive of secondary cases.[11] The simple cases usually lose their infectivity fairly rapidly. This is especially true since the introduction of "sulfa" and penicillin therapy, for a more complete eradication of streptococci from the nose and throat is now possible in a much shorter interval. Residents of the Minneapolis General Hospital have frequently been able to obtain negative nose and throat cultures as early as twenty-four hours after the onset of penicillin therapy. Spink et al suggest a five- to seven-day course of penicillin therapy for a more permanent eradication of streptococci.[24] We can, therefore, feel assured that, if modern therapy is administered, a seven-day isolation period could prove adequate for the control of the simple cases. The occasional secondary case that might result from a too early release of a scarlet fever patient would be amply compensated by the greater range or extent of control of all the hemolytic streptococcal infections that would be possible under a more liberal form of regulation.

The atypical nature of many of our hemolytic streptococcal infections makes it desirable to have available some laboratory measures which could aid the physician in his diagnosis. The identification of the specific group and type of hemolytic streptococcus concerned in each infection requires too much time to be of value in furthering early diagnosis, and is too complicated a procedure to be practiced on a large scale. Less difficult, however, is the bacteriological examination for hemolytic streptococci as a whole. This procedure can be performed quickly and easily, and is therefore a service that can be provided by most public health laboratories. It should be emphasized, however, that the diagnosis of hemolytic streptococcal infection should not be determined primarily by the laboratory culture. Less than 50 per cent of the initial cultures taken by the health department nurses from definitely diagnosed scarlet fever cases proved to be positive for the hemolytic streptococcus. Though a higher percentage of positives has usually been obtained from hospitalized patients, it is important to note that the finding of the hemolytic streptococcus in cultures is primarily of help in the formation of a

positive diagnosis, but that a negative culture does not necessarily imply the absence of such infection. Furthermore, if cultures are to be of aid in the detection of suspect cases or carriers, they should be taken from the nose as well as the throat. Hamburger has recently shown that hospital cross infections, infections in barracks, and food-borne epidemics of streptococcal pharyngitis or tonsillitis have frequently been traced to carriers with positive nose cultures who exhibit high "streptococcal outputs." He therefore feels that carriers of B hemolytic streptococci whose nose cultures are positive constitute a more dangerous group than those in whom the streptococci remain confined to the throat.[14]

Transmission

The transmission of streptococcal infections has generally been conceded to be primarily due to droplets spread in person-to-person contacts. Though epidemics have also been traced to food and milk contamination by streptococcal cases or carriers, the exclusion of infected persons from the handling of food or milk products and the pasteurization of milk supplies have practically eliminated this mode of transmission. The respiratory spread of streptococcal infections continues to be a major threat to our well-being. The prompt isolation and modern treatment of all known streptococcal diseases, however, may prove of definite value in limiting the spread of such infections. Still, Schwentker does not feel too optimistic over the possible benefit that can be derived from isolation of known cases, for he points out that for every known case there are a dozen unknown carriers. The attempt to recognize and segregate such carriers, he believes, is impractical; for, he says, "practically every person becomes a carrier of streptococci for at least a few days."[23] Nevertheless, the prompt treatment and isolation of all suspect and definite streptococcal cases could remove the source of most of these contaminations and thus minimize the possible number of secondary cases.

Although the direct method of spread by person to person contacts seems to be the primary mode of transmission of streptococcal infections, the indirect method cannot be entirely discounted. Of late, much interest has been redirected towards the potentialities of disease transmission through the inhalation of infected droplets. Such droplets, Wells has shown, can frequently remain suspended in the air for many hours; yet, until recently, the number of such floating organisms was believed to be too small to actually infect the average individual. Robertson, Hamburger et al, however, have recently shown that though the bacterial population of a room may be low at times when the air is undisturbed, i.e., at night, it can increase tremendously during such periods of disturbance as may occur during the peak of morning activities. This increase in bacterial content is usually occasioned during the process of bed making, sweeping, et cetera, when all those organisms which had previously been deposited on the bed clothes, floor, and pajamas, are again redispersed into the air. On culturing samples of air in the various wards, they found that the organisms which seemed to predominate in the air were identical with the types of hemolytic streptococci which were causing most of the secondary or cross infections prevalent in those wards.

Further study also revealed that it was the individual with positive nose cultures who usually expelled the largest number of organisms into the air, for, not infrequently, it was found that the presence of even one nasal carrier in a ward would produce a heavier contamination of the air and cause more cross infections than would be occasioned by large numbers of individuals harboring the streptococcus in their throats alone.[20]

Such findings could well explain why some individuals with scarlet fever, on being hospitalized, would later be affected by complications due to an entirely different type of hemolytic streptococcus than the one found upon admission. Such findings now revealed why a scarlet fever patient who would develop rhinitis or sinusitis was more likely to cause secondary cases than one who was free of such complications. Such observations are also suggestive of the mechanism by which epidemics may occasionally sweep through an institution even though the finest type of contagious technique seemed to be observed.

Recognition of the airborne route as a potential mode of spread of respiratory and wound infections has led to various suggestions for its control. Such suggestions include both methods for the prevention of the dispersal of organisms into the air, as well as measures for the disinfection of the air. Numerous experiments testing the effectiveness of such measures have been instituted, and

though conclusive evidence is not yet at hand, suggestive data has already been accumulated. Thus, Robertson et al have shown that by oiling the floors of various barracks, they were able to reduce the number of airborne bacteria by approximately 70 per cent; while if, in addition, the bedding was also oiled, a further reduction of about 90 per cent of the bacterial counts was obtained. How effective this radical reduction in airborne bacteria could be for the prevention of respiratory infections due to streptococci has not yet been fully determined. Robertson claims, however, that the results obtained thus far in his experiments point to a significant reduction in the number of hospital admissions for acute respiratory diseases from barracks in which the bedding and floors were oiled.[20]

Further control of air contamination has also been attempted through air disinfection. For this purpose, ultraviolet radiation and the use of certain glycol vapors have been most commonly employed.

Studies made by Wells in Philadelphia suggest that ultraviolet irradiation of class rooms can be of material aid in minimizing the spread of respiratory diseases.[26] Recent attempts, however, by Perkins to confirm such findings were unsuccessful.[19] A detailed study of this problem was also made by Wheeler. Evaluation of his results reveals a definite reduction in catarrhal infections, but fails to demonstrate any significant reduction in streptococcal infections following the use of ultraviolet irradiation.[27] Various attempts have also been made to evaluate the effects of glycol vapors for the prevention of cross infections. Most of these studies have been made by various members of the Commission on Airborne Infections.[17] Results obtained thus far have been far from conclusive. Much more work seems necessary, therefore, before any definite opinion can be formed concerning the effectiveness of the above methods of air disinfection.

Susceptibility

Although streptococcal infections are exceedingly mild and of rare occurrence in tropical areas, they increase greatly in incidence and severity in northern latitudes. Variations in the occurrence and severity of this disease are even noted in the northern areas, for the number of such infections start increasing in fall, reach their peak in late winter, and then steadily decline until the summer season, at which time the disease becomes markedly reduced both in incidence and severity. Whether such variations in reaction are due to a fluctuation in the resistance of the host or rather to changes in the virulence of the invading pathogen is unknown at this time. Valuable use, nevertheless, could be made of such observations. Such observations can be instrumental in directing the transfer of patients with rheumatic fever to regions which have a low incidence of streptococcal disease, and thus through the prevention of recurrent streptococcal infections minimize the number of heart complications. The decrease in virulence of streptococcal infections in summer could also warrant a shortened isolation period for the occasional case occurring in that season.

The limitation of streptococcal infections and the prevention of recurrent attacks of rheumatic fever have also been attempted through the administration of prophylactic doses of the "sulpha" drugs. Thomas, in reporting the results of a four-year study in which 1 gram of sulfanilamide had been administered daily to a group of adolescents and young adults, noted that none of those individuals getting sulfa suffered from any acute B hemolytic streptococcal infection or from any attacks of rheumatic fever, whereas both streptococcal infections and at least five rheumatic fever episodes were observed in the control group. The United States Navy likewise reported that the prophylactic administration of 1 gram of sulfadiazine to part of the personnel in several training centers for a period of four months resulted in the reduction of 80 to 90 per cent of those respiratory diseases requiring hospitalization, as well as a reduction of about 85 per cent of all streptococcal infections. As a consequence of the minimizing of streptococcal infections, they report that the incidence of rheumatic fever in such cases dropped sharply, for only about one case in the treated group occurred, as compared to fourteen cases observed among the control group.[25]

Prolonged use of the sulfa drugs, however, carries with it a number of potential hazards, chief of which are the toxic reactions that may be occasioned by the drug and the development of sulfa resistant strains of streptococci. More desirable, therefore, would be the building of resistance through immunization. Frequent attempts at such immunization have been made during the past four decades but, as yet, none has been more than partially successful. Immuni-

zation, if it is to be of value for the control of streptococcal disease, should develop resistance of fairly long duration, and should be effective against the infective as well as the toxic component of such infections. No immunization procedure thus far has been able to satisfy these requirements.

The development of antitoxin by the Dicks provided fairly adequate protection against the toxic effects of streptococcal infections. Its use was soon found to be not without danger and of limited value, for the protection provided was of short duration, and its use was frequently followed by serum reactions and sensitiveness to horse serum. A safer type of passive immunity has been made possible through the use of convalescent serum. Its disadvantages lie also in its brief protection and in the fact that it is difficult to obtain.

A more permanent type of protection, i.e., active immunization, can be established by the injection of graduated doses of Dick toxin. Until recently such procedure was believed to provide full protection against scarlet fever infection. More recent studies, however, have shown that this form of immunization develops protection only against the recognizable features of scarlet fever, for it provides immunity solely against the toxic component of that disease. As such, it has proved to be of definite value, and is able to effect a significant reduction in the case fatality rates of scarlet fever.

Nevertheless, if the various complications and dangers associated with streptococcal infections are to be avoided or minimized, active immunization procedures must develop resistance against the infective as well as its toxic component. Thus far, however, vaccines prepared to meet such need have proven inadequate.

Some authorities feel that the making of an effective streptococcal vaccine is well nigh impossible. They point out that streptococcal infections can recur quite frequently in the same individual and, therefore, any immunity thereby obtained must be very brief and inadequate. On the other hand, recent studies by DeWahl indicate that individuals who are exposed daily to massive doses of hemolytic streptococci can develop a high degree of immunity to those organisms.[3] Furthermore, experimental studies by Rothbard reveal that the antibodies which develop in the sera of patients convalescing from group A streptococcal infections are type specific and tend to first appear between three to five weeks following the onset of the infection. Such antibodies were found to persist in the sera for at least thirty-seven weeks.[21] The repeated occurrence of streptococcal infections in the same individual could therefore be better explained on the basis of fresh contacts with different strains of streptococci rather than to a lack of immunity to the same strain. The failure of previous vaccines can also now be better understood, for immunity to streptococcal infections appears to be largely type specific, and a vaccine, if it is to be effective, should be made up of those streptococcal types prevalent in the community in which it is to be used. The administration of such a vaccine, in the areas and during the seasons in which streptococcal infections seem to flourish, should be of definite aid in minimizing both the incidence and complications associated with this hitherto uncontrolled menace. The selective use of type-specific streptococcal vaccines can well become our most effective weapon for the future control of streptococcal disease.

Summary

New laboratory methods for the differentiation of the various hemolytic streptococci have been instrumental in the discovery of valuable additions to the epidemiology of scarlet fever. Consideration of scarlet fever in the light of such new experimental findings has resulted in an entirely new understanding of this disease. A brief review of such developments has therefore been presented and the following significant facts have been noted:

1. Scarlet fever can no longer be considered a specific infection, but is rather a disease syndrome caused by any one of a wide variety of hemolytic streptococci. Such syndrome represents the composite effect of two components, namely an infective and a toxic component. The infective component is responsible for those signs and symptoms which are common to all streptococcal infections, while the toxic component is responsible for the scarlatinaform rash. Whether a hemolytic streptococcus will occasion a streptococcal infection or a streptococcal infection accompanied by a rash is dependent both on the amount of erythrogenic toxin produced by such organism and on the amount of antitoxin present in the host. Thus, if sufficient toxin is produced

in a Dick-positive individual, scarlet fever will result. When such toxin is produced in a Dick-negative individual, a streptococcal infection without the rash will usually be occasioned. However, if little or no toxin is elaborated by the attacking pathogen, the resultant effect both in Dick-negative as well as in Dick-positive individuals will be that of a localized streptococcal infection.

2. Measures for the control of scarlet fever must therefore deal with all hemolytic streptococcal infections, and not simply with those which show a rash. Suggested measures for such control include the limitation of the reservoir of infection through the adoption of health regulations which require isolation procedures for all streptococcal infections, and not for scarlet fever alone. To promote effective co-operation with such a regulation, it may be advisable to institute a radical reduction in the isolation period of all such infections.

Further limitation of the spread of streptococcal infections has been attempted through the modification of its transmitting agents. Such measures have concerned themselves with the minimizing of the dispersal of organisms into the air, through the oiling of floors, bedding, et cetra, and the disinfection of the air with ultraviolet irradiation and the use of certain glycol vapors. Results thus far have been suggestive but not conclusive.

Most promising, however, for streptococcal control appears to be the promotion of individual immunity to streptococcal infections through vaccine administration. Previous failures of vaccine prophylaxis are now felt to have been due to lack of appreciation of the variable number of strains present in the hemolytic streptococcal group. Immunity to streptococcal infections appears to be type-specific. Vaccines to be effective must therefore be made up of such strains prevalent in the area in which they are to be used. The selective use of such vaccines can well become a most valuable aid for the control of streptococcal disease.

It has been estimated that nearly four per cent of all persons who visit physicians' offices complain of cough or expectoration. The alert physician will insist upon a sputum examination of all such patients. Such practice will be rewarded by the discovery of tubercle bacilli in three or four out of every 100 specimens examined. The family doctor will fairly often discover to his astonishment that a patient with slowly resolving pneumonia has an acid-fast reason for prolonged convalescence.—Herman E. Hilleboe, M.D., *Journal-Lancet*, June, 1947.

OSLER IN MINNESOTA

His Interest in Medical Education and Licensure

JAMES ECKMAN, Ph.D.
Rochester, Minnesota

I dare say that in a few generations Osler will be as soundly forgotten as Thomas Watson or even William Jenner, that he will be at most an occasionally cited name. Kind-hearted, honourable gentlemen are common enough to escape a bookish immortality.

—MAJOR GREENWOOD[19]

FIFTY-SIX years ago, William Osler (Fig. 1), just returned to the United States after a wedding trip to England, came out to the University of Minnesota to deliver an address, on October 4, 1892, at the dedication of a new medical building.[12] The next day he spoke, perhaps extemporaneously, before the Minnesota Academy of Medicine in Saint Paul.[43]

Much information concerning this visit by the distinguished internist of Johns Hopkins can be obtained from contemporary sources. But the writer has been uncommonly fortunate in that he has been accorded an advantage conferred upon few historians: the testimony of one who both knew the historical figure concerned and was a witness of the event in question.[65] The late Dr. Frederick J. Wulling (1866-1947), dean emeritus of the College of Pharmacy of the University of Minnesota, became acquainted with Osler in 1889, when Dr. Wulling was an associate of Dr. Samuel Fleet Speir (1838-1896), in Brooklyn, New York. Three years later, when Osler came to the University of Minnesota to dedicate the medical building, he remembered Dr. Wulling at once and greeted him cordially. The two men sat at the same table at the ceremonies—Cyrus Northrop, Governor Merriam and former Governor Pillsbury on one side, and the four deans, Dr. Millard, Dr. Brazie, Dr. Sudduth and Dr. Wulling, on the other. Whatever value this essay may be found to possess has, consequently, been immeasurably enhanced by the material which Dr. Wulling[65] has most generously supplied.

In itself, the visit of Osler to Minnesota is of no particular moment, for the postliminous journeys of the eminent are not, as a rule, calculated to derange the fortunes of commonwealths. What Osler said, on the other hand, considered in the light of medicine and medical practice in Minnesota at the time of his remarks, may be of considerable interest and some value. Minnesota in 1892 had been a member of the Federal Union for only thirty-four years. And although territorial legislators had thoughtfully provided for a medical school in the University of Minnesota in 1851,[2] a department of medicine had not been established until 1883—a department of medicine which was empowered to confer the degrees of bachelor of medicine and doctor of medicine but which actually had no students and offered no courses![9,62*]

The University Address

The building which Osler was to help dedicate is, according to Professor Schmeckebier,[56] a Renaissance type of edifice (Fig. 2). It was erected at a cost of $61,000[23] by L. Lund, Contractor, in 1892.† Both Greene[18] and Beard[10] wrote that Dr. Perry H. Millard (1848-1897), first dean of the University of Minnesota College of Medicine and Surgery, whom President Cyrus Northrop is said[18] to have called "a lesser Napoleon," advanced the money from his own pocket to pay for the structure.° At one side of the entrance

*Because, as will be shown herein, the only function of the University of Minnesota Department of Medicine when it was created in 1883 was to examine candidates for the license to practice medicine in Minnesota. The Department of Medicine could confer the degree of bachelor of medicine upon any candidate who passed the examination offered by the faculty, and "To the graduate in medicine it offered the further degree of M.D. upon the presentation and satisfactory defense of an approved thesis." See references.[9, 62]

†Ground for the new building apparently was broken in August or September, 1891. President Northrop of the University of Minnesota was said to have declared, at that time, that the building would be ready for occupancy "by the first of next year," which would be 1892. The building was not even completed, however, when Osler helped to dedicate it on October 4, 1892. See: The University of Minnesota. *Northwestern Medical Journal*, 19:143, (Sept.) 1891.

°Section 10 of chapter 163 of the general laws of Minnesota of 1891 appropriated $80,000 for new buildings for the University of Minnesota, the money to be derived "from any other funds in the state treasury not otherwise appropriated." Half of this amount was to be made available on April 1, 1892; the other half was to be made available on April 1, 1893. The state treasurer announced that in 1891 the sum of $73,488.03 had been paid by him to the university for buildings; in his report for 1892 he said that he had paid to the university for buildings the sum of $36,247.49. See: *General Laws of the State of Minnesota Passed During the Twenty-Seventh Session of the State Legislature Commencing January Eighth, One Thousand Eight Hundred and Ninety-One.* Saint Paul: Pioneer Press Co., 1891, p. 378. See also: *Annual Report of the State Treasurer of Minnesota, for the Fiscal Year Ending July 31, 1891.* Minneapolis: Harrison and Smith, State Printers, 1891, p. 75. See also: *Annual Report of the State Treasurer, of Minnesota, for the Fiscal Year Ending July 31, 1892.* Minneapolis: Harrison and Smith, State Printers, 1892, p. 75.

From the Division of Publications, the Mayo Clinic.

is a carved inscription which discloses that the building was designed by Reed and Stem of Saint Paul, a well-known architectural firm composed of Charles A. Reed (1858-1911) and Allen H. Stem (1856-1931). This firm, founded in 1892, later designed the Saint Paul Hotel, Saint Paul Auditorium, Metropolitan Opera House of Saint Paul and the Grand Central Terminal in New York City.[54**] The building which Osler dedicated still stands on the university campus. It has been occupied by the College of Pharmacy since 1912, after reconstruction made necessary by a fire which destroyed virtually everything but the walls.[65] On January 9, 1942, the Board of Regents of the University of Minnesota gave the name, "Wulling Hall," to the building.[65]

The writer has not been able to answer the question of who actually invited Osler to make the dedicating address,†† but the occasion very evidently was considered to be of major importance. One newspaper[51] noted that the Board of Regents of the university had sent out 4,000 special invitations to the proceedings, but that since the main lecture room in the new building would accommodate only 500 persons, "hosts of people were unable to take part in the exercises." It is curious to notice that after such energetic preparations on the part of the Regents, most of them were not there.[65]

The program was to begin at 8:00 p.m., but the lecture room was already filled at an early hour.[32] The *Minneapolis Tribune*[33] was uncommonly eloquent:

> If old Esculapius, god of medicine, still lingers about looking after the welfare of humanity, he must needs have been pleased last night. For over on the State University campus there was being dedicated to him a new temple. In point of architecture and equipment, this new medical building is not to be surpassed, and its dedication marks another stride in the advance of Minnesota's university. Since first the medical course was taken off paper and made a reality, the college was cramped into an inconvenient building, now the Asbury Hospital, and the students labored under great disvantage [*sic*]. But the new quarters are commodious and modern and the medics are jolly over the prospects.

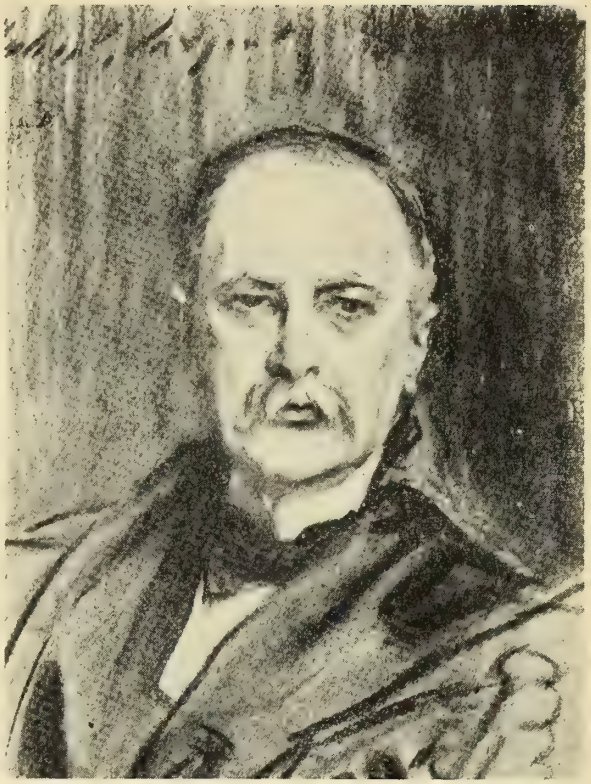

Fig. 1. Sir William Osler, after a charcoal portrait by the noted American artist, John Singer Sargent (1856-1925). Reproduced by permission of the College of Physicians of Philadelphia.

The Reverend Wayland Hoyt (1838-1910), pastor of the First Baptist Church of Minneapolis, opened the ceremonies with a prayer. Governor William R. Merriam (1849-1931) then briefly presented the building to the president of the Board of Regents, former Governor John S. Pillsbury (1827-1901). Cyrus Northrop (1834-1922), president of the University of Minnesota, next introduced, successively, Dr. Perry H. Millard (1848-1897), dean of the College of Medicine and Surgery; Dr. Henry W. Brazie (1843-1927), dean of the College of Homœopathic Medicine and Surgery; Dr. W. Xavier Sudduth (1853-1915), dean of the College of Dentistry; and Dr. Frederick J. Wulling, dean of the College of Pharmacy. Each man gave a brief address. President Northrop then introduced Professor Osler, remarking that since no other institution in the United States had done so much for university work as Johns Hopkins had done, it was fitting that Professor Osler should speak on the occasion at hand.[32]

**Some account of the work of these two Saint Paul architects is to be found in: Marshall, David: *Grand Central.* New York: McGraw-Hill Book Co., Inc., 1946, pp. 248-260.

††The writer had assumed that since the Board of Regents had sent out 4,000 invitations to the event, the Regents probably had invited Osler to speak at the ceremonies. This assumption, it turns out, cannot be proved. The minutes of the proceedings of the Board of Regents are kept in manuscript record books in the office of the comptroller of the University of Minnesota. Proceedings from March, 1868 to 1904 are contained in a volume marked "B 1." On July 10, 1947, W. T. Middlebrook, vice president of the University of Minnesota, advised A. J. Lobb, regent of the University of Minnesota, that search of book "B 1" of the proceedings of the Board of Regents produced no reference to either Osler or the dedication of the building in question in 1892. This information was placed in the hands of the writer by Mr. Lobb.

The circumstances under which Osler was to speak were not so tranquil as one might think now, fifty-six years after the event. He was not visiting a long-established medical school. On the contrary, the faculty before which he spoke had been in existence only four years, and had actually offered courses of instruction for only three years.[10,11,‡] It had come into existence as a result of the amalgamation, in 1888, of the old Saint Paul Medical College, the Minnesota Hospital College of Minneapolis, and the Minnesota Homœopathic Medical College of Minneapolis,[10] largely, it was said, as a result of the labors of its first dean, Dr. Millard.* The professors, ostensibly united as the faculty of the University of Minnesota College of Medicine and Surgery and the College of Homœopathic Medicine and Surgery, naturally could not have been unmindful of the institutions which they had seen obliterated by the union. Divers problems, uncertainties, perhaps even smoldering animosities, must have pervaded the minds of some of the men who had assembled to listen to the words of the celebrated internist from the Johns Hopkins University.

Osler perforce addressed two separate medical faculties that night: the so-called regular medical faculty and the homeopathic medical faculty. The deans of both of these faculties—Perry H. Millard and Henry W. Brazie—were speakers on the same program of which Osler was the major figure.[32,65]

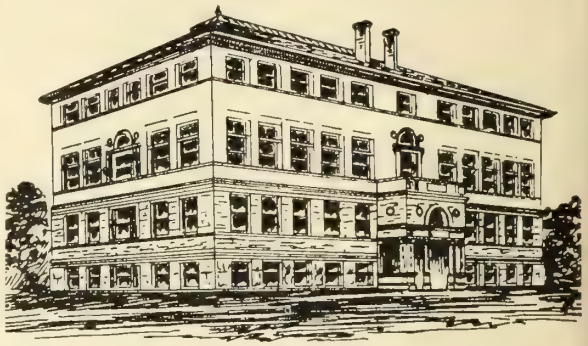

Fig. 2. The medical building at the University of Minnesota which William Osler helped to dedicate on October 4, 1892. This building was burned almost to the walls in 1912, but was rebuilt and thereafter was occupied by the College of Pharmacy. Since 1942 it has been known as Wulling Hall. Drawing from the *Minneapolis Times*, October 5, 1892.

The power of the so-called regular medical faculty was unquestionable, but the strength of the homeopathic practitioners at this particular point in the history of Minnesota cannot be dismissed abruptly. In 1892 homeopathic physicians had had a state society for a quarter of a century.[14,20] At the time, they had two medical journals† of their own, and the *Medical Argus* observed[35] that the homeopathic faculty at the university was planning a third. The homeopaths had had two other medical journals° previously, not including the *Transactions* of their state organization.[15,20] They had a number of homeopathic hospitals. They had had a homeopathic medical college, separate from university control.[15] Only five years before Osler's visit they had had sufficient political power to assure themselves, by act of legislature, of two of the nine members of the reorganized Minnesota State Board of Medical Examiners[5]; as late as seventeen years after Osler's visit they were still powerful enough to assure inclusion, in the appropriation for the expenses of the state government, of a section** which gave them $50,000 with which to erect a new medical building of their own on the campus

‡The College of Medicine and Surgery and the College of Homœopathic Medicine and Surgery of the University of Minnesota were formed in 1888, when the Saint Paul Medical College, the Minnesota Hospital College of Minneapolis, and the Minnesota Homœopathic Medical College of Minneapolis surrendered their charters as a requisite for amalgamation within the University of Minnesota. In 1888 the course of lectures at the College of Medicine and Surgery consisted of a term of three scholastic years, each scholastic year consisting of six months. In 1890 the scholastic year was extended so that it consisted of eight months. In 1894 the term was increased to four years. In the scholastic year of 1910-1911 it was announced that a fifth, or hospital, year would be required for the degree of doctor of medicine, this provision to become effective in the scholastic year of 1914-1915. Not long thereafter the University of Minnesota became one of the first institutions to require that the total period of instruction for a candidate for the degree of doctor of medicine be seven years, including the final year in internship. The degree of bachelor of science or bachelor of arts became a prerequisite to the degree of doctor of medicine; such a baccalaureate could be gained by two years of study in the College of Science, Literature and the Arts and two years of work in the Medical School, or by three years in the arts college and one year in the Medical School. In 1913 the faculty of the Medical School was reorganized to make possible intensive teaching by salaried clinical teachers; private clinics were abolished, and clinical work was concentrated in the University Hospital and the several municipal hospitals. See: Beard, R. O.: An Inventory of the Progress of Medical Education in America and in Minnesota. *Journal-Lancet*, 35:607-609, (Nov. 1) 1915. See also: Rogers, J. T.: President's Address: Team Work. *Journal-Lancet*, 35:602-607, (Nov. 1) 1915.

*The old Minneapolis College of Physicians and Surgeons was opened in October, 1883, offering a three years' graded course consisting of six months' instruction each year. Proper preliminary preparation was required for entrance to the school. During the first five years of its existence, the Minneapolis College of Physicians and Surgeons neither examined its students at the end of the three-year course nor conferred a degree upon them; those who had completed the entire course were sent to the University of Minnesota Department of Medicine to be examined for a degree from that institution. In 1895 the Minneapolis College of Physicians and Surgeons became the department of Medicine of Hamline University, with a faculty of forty-one members. In 1907 and 1908 negotiations were undertaken for merger of the school with the University of Minnesota College of Medicine and Surgery. The merger was effected in March, 1908. See: Moore, J. T.: The College of Physicians and Surgeons. *Journal of the Minnesota State Medical Association and Northwestern Lancet*, 29:45-46, (Jan. 15) 1909.

†These were the *Medical Argus*, published from 1890 to 1898; and the *Minneapolis Homœopathic Magazine*, published from 1892 to 1902. See reference.[15]

°These were the *Minnesota Homœopath*, published in either 1858 or 1859; and the *Minnesota Medical Monthly*, published from 1886 to 1888. See reference.[15]

**Paragraphs 11 and 12 of section 35 of the session laws of 1909. See reference.[1]

of the University of Minnesota, plus $5,000 with which to maintain the building for one year.[1]†† Nineteen years after Osler spoke at the University of Minnesota, the determination of the homeopaths of the state was such that they introduced a bill in the Minnesota State Legislature which, had it been enacted, would have created either a department or a college of homeopathic medicine at the university.°°

What, then, did Osler say to an audience of which the individual convictions were so seriously divergent? He said very little that was remarkable, very little that was new, and nothing that was controversial. No other course was open to him. He condemned independent medical colleges,[44] but so did almost everyone else at that particular time. The president of the American Medical Association, for instance, had considered the thought important enough to be emphasized in his address[16] at the thirty-ninth annual session of the association at Cincinnati in 1888, and the *Journal* of that organization had commended him for his words.[47]

Osler had kind words for the "schools with university connexions," and he approved of what he called "the State schools, of which this college [presumably the University of Minnesota College of Medicine and Surgery] is one of the few examples" because he thought such schools exemplified recognition that medicine was one of the technical branches of learning which ought to be taught in an institution supported by the people at large.[44] This was a subject which Osler's great colleague at the Johns Hopkins University, William Henry Welch (1850-1934), had developed at considerable length in an address[63] given at Yale University in 1888, productive of national attention in the field of medical education.[61]

Osler said that the destiny of any institution rests not in great buildings or much equipment, but on the men who work in the halls of such a place and the ideals which they possess.[44] This was, as Osler disclosed, a notion he had taken from Cardinal Newman. It was also essentially the same thought which Thomas Henry Huxley (1825-1895) had presented to the students and faculty of the Johns Hopkins University during a lecture at that institution in 1876.[21]*‡

"Thoroughly equipped laboratories," Osler said, *"in charge of men, thoroughly equipped as teachers and investigators, is the most pressing want to-day in the medical schools of this country."*[44]

This probably was true in the United States in 1892 and for some years thereafter,† but it was, again, scarcely a new or even different notion. Shryock[57] has shown that in the German university system the value of laboratory research and teaching had been recognized, even as early as 1825, to such a degree that the Germans in that year created "the first genuine laboratories in the modern sense of the term—excepting only the older ones devoted to anatomy."

Welch[64] said that Liebig's laboratory, opened in 1825, was the one which exerted the greatest influence on the subsequent establishment and organization "of public scientific laboratories in general"; that the first physiological laboratory was that of Purkinje, opened in 1824; and that the first pathology laboratory was that of Virchow, founded in 1856. The first laboratory of clinical medicine provided with its own building and sufficiently equipped for research apparently was the William Pepper Laboratory of Clinical Medicine in Philadelphia, opened in 1895.[57,64]

Even in American universities, however, there were laboratory facilities long before Osler's hortatory remarks of 1892. Nor was it a physi-

††It was not built because the Board of Regents in May, 1909, after passage of the act in question, abolished the College of Homœopathic Medicine and Surgery. See reference [11] for details.

°°The measure was House File No. 315, "A Bill for an Act to Amend Section 1479 of the Revised Laws of Minnesota and Creating a College or Department of Homeopathic Medicine and Surgery," and it was introduced by Dr. Henry R. Diessner (1853-1935), of Waconia. See reference.[49]

*The appearance of Huxley as lecturer at this university in 1876 seems to have been greatly resented by the citizens of Baltimore, who had already feared that the new institution, so extensively devoted to the natural sciences, would be hostile to religion. The Baltimore *American* attacked Huxley as a champion of the theory of evolution, than which "there is no more frightful heresy extant," and when it was observed that his lecture was not preceded by a prayer, the fact was advanced as indication of the contempt of the new university for religion. See: French, J. C.: *A History of the University Founded by Johns Hopkins.* Baltimore: Johns Hopkins Press, 1946, pp. 82-83.

‡It is interesting to notice that in 1947 the president of the Johns Hopkins University inveighed against the ideas of both Huxley and Osler in this respect: "Opinions run in packs, and new private foundations are generally insisting that their policy is 'no money for bricks and mortar.' It seems so plausible to say, 'This money must go into productive work, not bricks and mortar. We want to see immediate results. We want to feel that our grant has created a new and useful piece of knowledge.' No one seems to see that the scholar does his best work when he is sheltered from rain and frost. We all remember the work on pitchblende that the Curies did in their search for radium, but we forget the hardships they endured in winter as they worked in a cold shed with a leaky roof. Someone, somewhere must build laboratories and classrooms, train young scholars, and hold to a steady course of support as promising men grow to maturity—or there will be no discoveries." See: Bowman, Isaiah: *The Johns Hopkins University: Report of the President, 1946-1947.* Baltimore, 1947, p. 29.

†For instance, one of the reasons advanced by the *St. Paul Medical Journal* for the passing of the Hamline University Medical School in 1908 was that the institution was deficient in anatomy, physiology, chemistry, pathology and bacteriology laboratories. "These laboratories, the Hamline school, which was a private corporation with very little capital, could not maintain as they should be maintained and with such a handicap it could not make good." See: The Passing of the Hamline Medical School. *St. Paul Medical Journal,* 10:211-212, (Apr.) 1908.

cian, according to Professor Nevins,[34] who led the way for reform of medical education in America. He identified Charles William Eliot (1834-1926), president of Harvard University, as the man who, against "an incredible weight of conservative opposition," in the early seventies not only insisted that the Harvard Medical School extend its schedule to three full years of eight or nine months each, but also demanded and secured the establishment of laboratory training in medicine and forced the medical faculty to give severe written examinations to the students.*

Schlesinger[55] wrote that between 1878 and 1898 in the United States, private benefaction added $140,000,000 to the funds available for higher education, so that "Amply equipped for the first time with tools of research—laboratories, instruments of precision, libraries, museums, observatories, hospitals—scholars and scientists in the United States were enabled to make a contribution to the world's learning fully comparable to that of the first nations of Europe."

So far as the University of Minnesota is concerned, it is noteworthy to discover that seventeen years after Osler's plea for laboratories and laboratory workers, W. J. Mayo declared that the prime need of the university was a clinical hospital.[27] This declaration was made in the course of a short address in which he did not once mention laboratories.

Half a century after Osler's remarks at the University of Minnesota, the laboratory apparently had assumed such fearsome proportions that perhaps even the Regius professor of medicine at Oxford would have reconsidered the fervor of his adjuration of 1892:

> The teaching of medicine as conducted today in the average medical school has brought forth a crop of young physicians who seem to depend too much on laboratory procedures. Much of the bedside teaching in these schools has drifted into the dialectics of mechanised and biochemical data. The rapid strides in biochemical studies, the extension of mechanical procedures in contrast to the good history and physical examination, has [*sic*] crowded out clinical perception and dulled clinical judgment.
>
> We must reverse this tendency and insist on a good analysis of a history and a physical examination before any laboratory investigations are done.[24]

*This apparently was a prospect which evoked deep consternation, for the dean of the Harvard Medical School is said to have exclaimed in 1870 that it was impossible to give written examinations in the medical school because "a majority of the students cannot write well enough." See reference.[34]

In the address of 1892 is discernible a conviction—"Insensibly, in the fifth and sixth decades, there begins to creep over most of us a change, noted physically among other ways [by] the silvering of the hair and that lessening of elasticity which impels a man to open rather than to vault a five-barred gate"[44]—which reached full expression thirteen years later in a farewell address Osler gave at the Johns Hopkins University on February 22, 1905.[45]**

After the address, most of the physicians in the audience lingered to attend an informal reception in honor of Osler.[65] Osler requested Dean Wulling to remain at his side, and asked him to repeat to him the names of some of the physicians whom Dean Millard presented to him. Dean Wulling recalled that on this occasion Osler seemed not to be as good a conversationalist as usual, but the Johns Hopkins professor responded cordially to each introduction, and at length remarked to Dean Wulling that he was glad to have made so many friends in Minnesota.[65]

The reactions to Osler's address were varied. A student in the College of Pharmacy who had just been graduated from a high school said it was the best speech he had ever heard; a student in the College of Dentistry thought Osler's words were "over his head"; a student in the College of Medicine and Surgery declared that Osler's remarks were addressed to minds inferior to those of medical students. President Northrop, a few days later, allowed that Osler's address was "good, for a medical man."[65] One Minneapolis newspaper said that Osler treated his subject in "an able and learned manner"[32]; another referred to the speech as "a masterly address."[33] Cushing[12] many years later adjudged the address to be one of the most effective Osler ever made.

**This was the famous piece which he called "The Fixed Period," after Anthony Trollope's novel, *The Fixed Period.* Osler's address created an uproar in the public prints because it was charged that he had urged that all men more than sixty years old should be chloroformed. Actually, he did not, as study of "The Fixed Period" will show. In 1906, writing from the relative security of Oxford, Osler explained his misjudged remarks of the previous year: ". . . to relieve a situation of singular sadness in parting from my dear colleagues of the Johns Hopkins University, I jokingly suggested for the relief of a senile professoriate an extension of Anthony Trollope's plan mentioned in his novel, *The Fixed Period.* To one who had all his life been devoted to old men, it was not a little distressing to be placarded in a world-wide way as their sworn enemy, and to every man over sixty whose spirit I may have thus unwittingly bruised, I tender my heartfelt regrets. Let me add, however, that the discussion which followed my remarks has not changed, but has rather strengthened my belief that the real work of life is done before the fortieth year and that after the sixtieth year it would be best for the world and best for themselves if men rested from their labours." See: Osler, William: *Aequinimitas, With other Addresses to Medical Students, Nurses and Practitioners of Medicine.* Philadelphia: P. Blakiston's Son and Co., 1920, ed. 2, p. viii.

Any critical analysis of Osler's remarks on this occasion should be made in the light of the situation in which he found himself on that evening. He was in the midst of strangers. He faced a divided audience: on the one side were the so-called regular faculty members; ranged against them were the numerically fewer homeopathic faculty members†† who nevertheless could rely upon powerful political support within the state. In other quarters of the university, the medical faculty and students were regarded as "barbarians" and the opening of the new medical building was viewed with disfavor if not alarm.[11]

Finally, the University of Minnesota itself was relatively new, with no great endowments or other forms of formidable resources, and as such was understandably sensitive to the opinions of a man associated with scholars as illustrious as those of the Johns Hopkins University. Considerations such as these must have passed through the mind of Osler as he faced the audience at the University of Minnesota on the October evening in 1892.

The Saint Paul Address

In Saint Paul, Osler was a guest of Dr. Albert E. Senkler (1842-1899), at the latter's home at 177 Virginia Avenue.[53]‡ On October 5, 1892, the evening of the day after the university address, Osler was entertained at the Minnesota Club, Fourth and Cedar Streets, by members of the Minnesota Academy of Medicine.[52] A list of the physicians who attended the meeting, as published in a Saint Paul newspaper the next day, includes the names of some of the most prominent practitioners in the state; they came from such distant places as Brainerd, Saint Cloud, Winona, Albert Lea, Northfield and Faribault, as well as Minneapolis and Saint Paul.[52] After the dinner, the guests adjourned to the House of Representatives in the State Capitol at Tenth and Wabasha Streets. There Osler spoke on "License to Practice."[43] His remarks were by no means new, for he had delivered much the same address in 1889 before the Medical and Chirurgical Faculty of the State of Maryland, and by the time he spoke in Saint Paul his address had already been printed in at least four different publications three years earlier.[39-42] The text of the Saint Paul address[43] does not conform *verbatim* to the text of the previous versions, for it is greatly condensed, but in a large part the substance is essentially identical.

He began by saying that it was a pleasure to elaborate this subject to physicians of Minnesota[43]—"a state which stands foremost in the attempt to regulate the practice of medicine." He had praised Minnesota in the same respect three years earlier.[39-42] Next, however, he deplored the fact that the United States was the only country in the world in which the doctorate carried with it the right to practice medicine.[43] Germany, he said, required the most rigid examination of all before a physician was admitted to practice; the German examination was, he thought, the "most thorough and systematic examination in medicine in the world."[43] In Great Britain the degrees of the Royal College of Physicians—which is not a teaching institution—as well as the degrees of certain older universities, constituted licenses to practice. Canada, Osler declared, had the best plan of all. Each province was divided into districts; in each district forty physicians were elected by their fellow practitioners, and constituted a board of control over medical matters. The board in turn appointed an examining body, before which must come all physicians who wished to practice medicine in the particular district. "I trust that the State of Minnesota," Osler concluded, "which has progressed so far in the restriction of medical education, will, with other states, go still farther and adopt the Canadian plan"[43]—the same plan he had praised in a previous address on the same subject in 1889.[39-42]

Why should Osler have chosen the subject of medical licensure at this time, and why did he twice commend Minnesota for the progress it had made in medical licensure? The answers to these questions may be found in a paper published in 1921 by Beard,[11] who revealed that he was a member of the legislative committee which drafted the Minnesota medical licensure act of 1887.[5] This act, Beard said, created "an independent Board of Medical Examiners under the first law of its type, known as the examination law, enacted

††In the first year of medical instruction in the University of Minnesota all students—so-called regular, homeopathic and dental—attended the same courses, in which only anatomy, physiology and chemistry were taught. At the end of this first year, the medical student could decide whether he wished to continue in the College of Medicine and Surgery or to enter the College of Homœopathic Medicine and Surgery. The three-year course was said to have been "modeled after that pursued at the Harvard Medical School." See: The Medical Department of the State University. *Northwestern Lancet*, 8:137, (May 15) 1888.

‡Greene in 1920 recalled Dr. Senkler as "that gifted, modest, all-around man, Dr. A. E. Senkler, the simplicity and clarity of whose lectures was [*sic*] the direct reflection of his analytic, orderly, and systematic modes of thought." See reference.[18]

in the United States. It discarded the diploma as an evidence of medical education. It required an examination of every applicant for license to practice medicine in Minnesota."[11] This was the law to which Osler alluded in his Saint Paul address[43] in 1892, and since it was said to be the first law of its kind enacted in the United States, it is not difficult to see why he should have displayed some enthusiasm over it.

Yet this licensing law of 1887, like most works of value, did not spring spontaneously from the Legislature of 1887. It had two largely unsatisfactory predecessors which must be understood before the act in question can be fully appreciated.

The history of medical licensure in Minnesota has not been written. Rush's thesis[50] of 1931 would appear to deal with the problem, for he announced that he proposed to "give something of the historical background [of medical licensure in Minnesota] where that seems to be necessary." Actually, however, Rush almost wholly ignored historical development when he investigated the licensing of practitioners of the healing arts in Minnesota.

It is of some moment to observe that even in territorial days, Minnesota contrived obliquely to regulate the practice of medicine to a slight degree. Chapter 19 of the revised statutes of 1851*† empowered county medical societies to examine medical students who were at least twenty-one years old, had "a good English education," had studied medicine for at least three years "with some respectable practitioner," and had a "good moral character."[37]†† The standard fee for such an examination was $10, which entitled the successful candidate to a diploma indicative of a membership within the society, signed by the president of the society. An additional fee not to exceed $3 could be charged by the society "for the purpose of procuring a medical library, anatomical cabinet, chemical apparatus, or for the encouragement of useful discoveries in the science of medicine."[37] It is to be noticed that this statute did not, however, pertain to licensure. A man was free to practice medicine in the territory, with or without the degree of doctor of medicine. In many respects, this statute of 1851 is not greatly different from one of 1781 in Massachusetts, which incorporated the Massachusetts Medical Society and provided for the examination of candidates for membership in that organization.[26]

The first state law which regulated the practice of medicine in Minnesota is found in chapter 41 of the general laws enacted by the Legislature of 1869.[3] This law, approved by Governor William R. Marshall (1825-1896) on March 9, 1869, likewise did not require the candidate for licensure to possess the degree of doctor of medicine. He could (1) have attended two full courses of medical instruction and been graduated from some school of medicine in either the United States or a foreign land, or (2) present a certificate of qualification from some state, district or county medical society. There was no examination of any kind. The candidate was obliged only to present his diploma or his certificate to the clerk of the district court of the district in which he practiced, by October 1, 1869. If he could not produce either document, he could not practice medicine in Minnesota. Violation of the statute was punishable by a fine of not less than $50 and not more than $100. A second violation could be punished by the fine plus incarceration for thirty days in the county jail in the county concerned.[26]

The statute was repealed by chapter 47 of the general laws of Minnesota passed by the Legislature of 1870, signed by Governor Marshall on February 24, 1870.[7] The law of 1869 is of some interest in that, according to sections 1 and 3, the State of Minnesota took official cognizance of certification of a candidate's qualifications by a medical society. Such a feature was by no means new, however, for in 1819 the State of Massachusetts by legislative act had authorized the Massachusetts Medical Society to appoint medical examiners in each county and to license those candidates who passed the examinations; each person licensed was to file his license in the office of the clerk of the

*Passage of this territorial statute concerning county medical societies would appear to strengthen, but not confirm, Armstrong's contention that a "Minnesota Medical Society" was organized in the Territory of Minnesota on July 23, 1853. The records of this territorial medical society, if indeed it existed, have not been found. See: Armstrong, J. M.: History of Medicine in Ramsey County. *Minnesota Medicine*, 22:251-257, (Apr.) 1939.

†This statute subsequently became sections 1 through 14 of chapter 17 of the public laws of the State of Minnesota, 1858, which chapter was entitled "Corporations, Their Formation and Regulation." See: *The Public Statutes of the State of Minnesota.* (1849-1858.) *Compiled by Moses Sherburne and William Hollinshead, Esqrs., Commissioners.* Saint Paul: Pioneer Printing Co., 1859, pp. 277-279.

††Section 5 of chapter 108 of the same statutes specifically mentioned physicians in another aspect of medical regulation: "If any physician or other person, while in a state of intoxication, shall prescribe any poison, drug or medicine, to another person, he shall be punished by imprisonment in the county jail not more than one year, or by fine not exceeding five hundred dollars." See: *The Revised Statutes of the Territory of Minnesota, Passed at the Second Session of the Legislative Assembly, Commencing January 1, 1851.* Saint Paul: James M. Goodhue, Territorial Printer, 1851, p. 521.

town in which the man proposed to practice.[26] This brings to mind a rather formidable power enjoyed by the old Minnesota State Homœopathic Institute: that of conferring the degree of doctor of medicine on any member considered by the censors worthy of the honor. Dr. H. A. L. Von Wedelstaedt (1817-1900), of Saint Paul, received such a degree in 1867.[14,17]

Between 1870 and 1883 there was no regulation of the practice of medicine by the State of Minnesota. Chapter 125 of the general laws of Minnesota of 1883 is the so-called diploma law,[4] signed by Governor Lucius F. Hubbard (1836-1913) on March 5, 1883. The essential features of this law, according to Millard,[31] who Greene[18] said was responsible for the introduction and passage of the bill to create the act, were copied from the Illinois licensing law[22,30,46] which became operative on July 1, 1877.** Section 2 of this statute required the University of Minnesota Department of Medicine to organize itself as a board of medical examiners. If a man had a valid diploma demonstrating that he was a doctor of medicine, he was licensed at once; if he had no diploma,†† he was to be examined before the board. Each man licensed by the presentation of a diploma paid a fee of $1; each man licensed by examination paid a fee of $5. The person licensed was given a certificate from the board which he recorded in the clerk's office of the county in which he resided.[4]

The penalty for neglect or refusal to comply with this act was a fine of not less than $50 and not more than $500, or incarceration in the county jail for not less than thirty days or not more than 365 days, or both the fine and the imprisonment. Any physician who had been practicing medicine in Minnesota for five years at the time the bill became law was exempted from its provisions.[4]

The constitutionality of this law was argued before the Minnesota State Supreme Court°° in 1884 and 1885,[13,58-60] but the law was upheld by the court in all particulars.*

It is seen, then, that the present University of Minnesota Medical School, actually created by the Board of Regents on January 5, 1883,† came into existence to function solely as a state board of

°°Briefs in the cases in question are on file in the Minnesota State Library in the Capitol in Saint Paul.

*In the first instance, Dr. David F. Powell of La Crosse, Wisconsin, presented his diploma from the Louisville Medical College dated February 28, 1873. The Minnesota State Board of Medical Examiners found that the diploma was genuine, but that Dr. Powell, by advertising himself in newspapers and circulars as a medicine man of the Winnebago Indians, adopted by them and styling himself "White Beaver," and claiming that he had a remedy which would cure cholera morbus if taken internally and rheumatism if applied externally, had been guilty of unprofessional and dishonorable conduct. The board therefore refused to issue a license to Dr. Powell. Dr. Powell thereupon obtained an alternative writ of mandamus from the Ramsey County District Court which would have required the Minnesota State Board of Medical Examiners to issue a license to him. The Minnesota Supreme Court on July 19, 1884, handed down the decision that (1) Dr. Powell had the right to be heard on the subject of the investigation of his conduct by the board, (2) the word "unprofessional" in section 9 of the Act of 1883 was used convertibly with "dishonorable," and had a like meaning, (3) the act itself was not unconstitutional, and (4) Dr. Powell was not entitled to remedy by mandamus to secure review of the correctness, or the reversal, of the determination of the board. See reference.[58]

In the second instance, the challenge of the act by the plaintiff, Dr. Edward D. Chapman, was based on curious reasoning. He had been licensed by the Minnesota State Board of Medical Examiners, but in June of 1885 the board had served written notice upon him of unprofessional and dishonorable conduct, and had notified him to appear before the board to show why his license should not be revoked. Dr. Chapman obtained a writ of prohibition against the board, and asked to have it made permanent. He argued that the license to practice medicine, once granted, was private property, and that revocation of such a license was exercise of judicial power, which he alleged could not be vested in any executive or administrative board or even in the Legislature itself, but only in the courts. Hence, he said, to assume to vest this power in a state board was to deprive persons of private property without due process of law, and violated the Constitution of Minnesota. The Minnesota Supreme Court on December 24, 1885, held that the revocation of a license to practice medicine in Minnesota by the Minnesota State Board of Medical Examiners was not an exercise of judicial power, and that, hence, the power of revocation of such a license could, constitutionally, be vested in the board in question. See reference.[59]

In the third instance, Dr. E. C. Feller had applied for a writ of prohibition to restrain the Minnesota State Board of Medical Examiners from further action in proceedings instituted to revoke, on the ground of alleged unprofessional and dishonorable conduct, a certificate issued to Dr. Feller enabling him to practice medicine in Minnesota. Dr. Feller had held that his conduct was a breach of professional ethics only, and was not unprofessional or dishonorable. The medical examiners had held that Dr. Feller, in claiming to be able to cure *all chronic* nervous diseases and diseases of the blood and skin of both sexes, *all* diseases of the eyes and ears without the use of injurious drugs or hindrance of the patient from business, *all* old, lingering constitutional diseases, and his use of terms such as *cured for life*, had published false statements which he knew to be false. The medical examiners held that Dr. Feller had published such statements *"with intent to deceive and impose on the public.* If true, this is unprofessional and dishonorable conduct of the grossest kind." Dr. Feller also charged that the board of medical examiners had exceeded its authority because it had cited him to show cause not only why his certificate should not be revoked, but also why he should not be debarred *forever* from the practice of medicine in Minnesota. The Minnesota Supreme Court, however, quashed Dr. Feller's application for a writ of prohibition, remarking that if Dr. Feller's certificate were revoked by the board, the legal effect would be forever to debar him from the practice of medicine in Minnesota, unless the statute itself were revoked or unless a new certificate were issued to him. See reference.[60]

**Comparison of the text of the Minnesota law of 1883 with the Illinois law of 1877 shows that in some sections the text is identical. Millard himself wrote (reference [31]) that the Minnesota law of 1883 was "a verbatim copy of the present Illinois Act, except that the exemption clause was five years instead of ten, which is the period of exemption of the Illinois Act." The two acts also differed in the nature of the licensing bodies and in penalties for violation of the law.

††The University of Minnesota Department of Medicine, apart from its powers as the state board of medical examiners as conferred by the law of 1883, could grant the degree of doctor of medicine to such persons as were able to qualify for the degree. The old Minneapolis College of Physicians and Surgeons, which opened in October, 1883, for the first five years of its existence did not grant the degree of doctor of medicine to any of its graduates; instead, it sent them to the University of Minnesota for graduation. Hence, graduates of the Minneapolis College of Physicians and Surgeons during that period received the doctorate in medicine from the University of Minnesota. See: Moore, J. T.: The College of Physicians and Surgeons. *Journal of the Minnesota State Medical Association and Northwestern Lancet*, 29:45-46, (Jan. 15) 1909.

†The Board of Regents, in creating the Department of Medicine, are said to have adopted the plan submitted to the Board on June 29, 1882, by Dr. William Watts Folwell (1833-1929), then president of the University of Minnesota; Dr. William H. Leonard (1825-1907), a pioneer homeopathic physician of Minneapolis; and Dr. Charles N. Hewitt (1835-1910), of Red Wing, founder of the Minnesota State Board of Health and Vital Statistics in 1872. See: Folwell, W. W.: *A History of Minnesota.* Saint Paul: Minnesota Historical Society, 1930, vol. 4, pp. 422-423.

medical examiners,[62] for the school as then organized offered no courses. Beard[9,10,11] wrote that the legal origin of the University of Minnesota Medical School was "the state constitution of 1853," but this is palpably an error, for Minnesota was not a state in 1853, and had no state constitution prior to 1857, as the monograph by Anderson and Lobb[8] plainly shows. Rather, the University of Minnesota Department of Medicine was specifically provided for in section 10 of chapter 3 of the territorial laws of 1851[2]; this was affirmed in section 10 of the revised territorial laws of 1851[38] and in section 2 of chapter 1 of the general laws of Minnesota of 1868,[6] as well as in section 2 of chapter 125 of the general laws of Minnesota of 1883.††[4]

But it was the licensure law of 1887[5] which drew Osler's attention and commendation. As chairman of a committee appointed to study medical licensure in the United States, Millard[30] in 1889 told members of the American Medical Association that he himself had drafted the bill to create the act of 1887, on the basis of some five years' experience as executive officer of the old board brought into existence by the previous act of 1883.** The act of 1887, in which Beard[11] also seems to have had a hand,†† was signed by Governor Alexander R. McGill (1840-1905) on February 28, 1887.[5,28,48] The law provided for a board of nine medical examiners, each of whom was to serve for three years, with the exception of those nine persons who constituted the original membership of the board. Of the latter, three were to serve for one year, three were to serve for two years, and three were to serve for three years, from the date of appointment by the governor. No member could serve for more than two terms; no member could be a member of any college or university which had a medical department.[5] The latter provision thus effectively prevented any member of the old board of medical examiners, created by the act of 1883 and still in existence up to the time of application of the act of 1887, from being appointed to the new board.°°

The first section of the law of 1887 required that two members of the board be homeopathic physicians,* but nothing whatever was said as to the qualifications of the other seven members; it was not even necessary legally, that they be physicians—an objection promptly pointed out by the *Journal of the American Medical Association.*[29] "The Governor . . . has taken the clause providing that two of the board shall be homeopaths to mean that there shall be just two homeopaths appointed and no more, and has followed that interpretation in these appointments," the *Northwestern Lancet*[36] observed.

The law of 1887 required anyone who wished to practice medicine or surgery in Minnesota to apply to the board of medical examiners for a license.[5] The candidate had (1) to undergo examination in a number of branches of medicine and the basic sciences† and (2) to present evidence of his or her attendance at three courses of lectures of at least six months each. A license to practice medicine could be granted only by consent of no fewer than seven of the nine examiners. A license could be revoked for "unprofessional, dishonorable or immoral conduct." Once granted, the license had to be filed with the clerk of court of the county in which the applicant proposed to

††But the Department of Medicine was not mentioned in chapter 80 of the general laws of Minnesota of 1860, which chapter provided for the government and regulation of the University of Minnesota. Section 10 of this law merely provided that "The University shall consist of such departments as the Board of Regents shall determine, subject to the provisions of this Act, and the same may be altered or changed as they may prescribe." See: An Act providing for the Government and Regulation of the University of Minnesota. In: *General Laws of the State of Minnesota, Passed and Approved during the Second Session of the State Legislature, commencing December seventh, One Thousand Eight Hundred and Fifty-Nine, and Terminating March Twelfth, One Thousand Eight Hundred and Sixty.* Faribault: Orville Brown, State Printer, 1860, pp. 264-268.

**In 1887 Millard was first vice president of the American Medical Association. Speaking before the Section on State Medicine of the association in that year, he remarked: "We have not an ideal Medical Practice Act in any State in the Union. The nearest approach thereto is the new Act of Minnesota. By the provision of this Act, every person commencing the practice of medicine must pass an examination and furnish satisfactory evidence of having taken three full courses of lectures of not less than six months' duration each." See: Millard, P. H.: The Propriety and Necessity of State Regulation of Medical Practice. *Journal of the American Medical Association,* 9:491-493, (Oct. 15) 1887.

††Actually, the bill to create the law of 1887 seems to have been framed by a joint committee of physicians of both the homeopathic and so-called regular persuasions. Dr. Chester Goss Higbee (1835-1908), a homeopathic practitioner, writing in the old *Medical Argus* of Minneapolis in 1893, declared that he "was a member of the joint committee of the two dominent [*sic*] schools of medicine, that framed the bill" of 1887. Dr. Higbee complained bitterly that someone had substituted an "and" for an "or" after the bill had been agreed upon by this joint committee, and he charged that what would have been simply a law permitting licensure by diploma had, by the substituted conjunction, been converted covertly into a law which required graduation from a reputable medical college and also examination by the board of medical examiners. See: Higbee, C. G.: The Medical Law of Minnesota. *Medical Argus,* 3:137-138, (Mar.) 1893.

°°Members of the old Minnesota State Board of Medical Examiners created in 1883 met for the last time in the State Capitol in Saint Paul on July 5, 1887; members of the new Minnesota State Board of Medical Examiners created by the act of 1887 met for the first time in the same place at the same time. See: *Northwestern Lancet,* 6:375-376, (July 1) 1887.

*Governor McGill appointed, in fulfillment of this particular clause, Dr. Henry C. Leonard (1849-1925) of Fergus Falls, and Dr. Frederick C. Bowman (1849-1938) of Duluth.

†In anatomy, physiology, chemistry, histology, materia medica, therapeutics, preventive medicine, practice of medicine, surgery, obstetrics, diseases of women and children, diseases of the nervous system, diseases of the eyes and ears, medical jurisprudence "and such other branches as the board shall deem advisable."

practice. Once a year each clerk of court had to send a list of all certificates on file in his office to the secretary of the Minnesota State Board of Medical Examiners, and the record kept by each clerk of court had to agree with the record for that county maintained by the secretary of the state board.

Physicians commissioned in the army or navy, physicians called to Minnesota for consultation from other states, and medical students practicing medicine under the direct guidance of a preceptor were exempt from the provisions of the act. Those physicians who had been licensed under the act of 1883 were automatically licensed by the act of 1887,[5] which repealed the law of 1883.[4]

Anyone who practiced medicine or surgery in Minnesota without a license from the new board, or who practiced contrary to the provisions of the act of 1887, was to be considered guilty of a misdemeanor and, if convicted thereof, could be fined not less than $50 nor more than $100, or could be imprisoned in the county jail for not less than ten days nor more than ninety days.[5] Both fine and imprisonment could be imposed on an offender. Justices of the peace and the respective municipal courts had jurisdiction over violations of the act; the respective county attorneys were to prosecute offenders.

Osler in his more extended remarks of 1889[39-42] had recognized that the power to regulate the practice of medicine rests with the state. But he had not approved of the practice whereby the governor of a state or the medical societies thereof appointed the medical examiners: "Theoretically, there can be no question (particularly in democratic communities) that a State board should be elective, not appointed by the Governor or the societies."[40]

What Osler wanted must be set forth in terms of the three different ways in which a physician might be licensed: (1) by the simple presentation of a diploma, (2) by examination of the candidate before a board of medical examiners appointed by the governor of a state or by the medical societies thereof, and (3) by examination of the candidate before a board of medical examiners elected by physicians themselves.

In 1889 Osler had abhorred the first scheme and had not been enthusiastic about the second one, but the third had won his untempered favor.[40] In 1892, three years later, his views were essentially the same,[43] yet it is patent that it is licensure by a state board appointed by the governor which prevails today, and not licensure by boards elected by physicians.

Osler's plan for licensure would have removed the regulation of medical practice further away from the sphere of the state government, and therefore from governmental jurisdiction, for his ideal "medical parliament" would not be concerned merely with licensure. It would, first, regulate "the minimum standard of education required in entering the profession."[40] Second, it would examine and license candidates for the practice of medicine. Third, it would carry out prosecution of irregular and unlicensed physicians and "exercise such additional powers as might, in the opinion of the framers of the bill, be thought justifiable." All these powers would reside in the elective "medical parliament" which Osler advocated.

Actually, however, Osler's "medical parliament" would possess what might be called plenary powers, for it would "take cognizance of all matters related to medical education, and, perhaps, although of this I am not so sure, of questions of public health within the State."[40] Such a concept seems rather distant from the theory of democratic control which Osler had advanced at the outset, for in its widest implications it would combine legislative, judicial and executive functions, to the exclusion of those representatives of the people who are elected by the ballots of all citizens.

The *Journal of the American Medical Association,* commenting on Osler's views in 1889, was quick to perceive the superiorities of a system in which the laws of the state itself would guide the actions of the state board of medical examiners, regardless of whether the examiners were appointed by the governor or elected by physicians legally authorized to practice.[25]

This journal, moreover, elaborated two points which it believed Osler had not considered sufficiently: (1) that any state board of medical examiners, however constituted, would fail unless the law of the state explicitly defined the minimal standard of general education necessary for entrance upon the study of medicine and also defined the minimal standard of medical requirements necessary for practice, and (2) that the powers of any state board of medical examiners should be purely executive and not legislative.[25]

The Saint Paul address of 1892[43] is much shorter than that of 1889[40]; it occupies but a single page in the *Northwestern Lancet*. But the central theme of a "medical parliament" appears once again, and strongly. "The election of a medical parliament by the medical profession to control medical affairs is alike to the interest of the practioner and the public."[43] He hoped Minnesota would create such a parliament as the state medical licensing body.[43]

Another thought advanced by Osler in his address of 1889[40] also drew the fire of the *Journal of the American Medical Association*.[25] Osler had proposed that all physicians, whatever their persuasion or training, be subjected to the same examination for licensure, with the single exception of the section devoted to therapeutics. In therapeutics, he thought, an eclectic physician might be examined in eclectic therapeutics; a regular physician might be examined in regular therapeutics; a homeopathic physician might be examined in homeopathic therapeutics.

This was untenable to the *Journal of the American Medical Association:* "On the contrary, every applicant should be examined and be required to furnish evidence of having a fair knowledge of all systems. No student of regular medicine should be licensed to practice unless he also understands clearly the distinctive facts and principles of homeopathy, eclecticism, and every other *ism* that he is to come in contact with among the people. And no student of any one of these pathys or isms should receive a license to practice unless he is also possessed of a good knowledge of the regular therapeutics as practiced by more than nine-tenths of the medical men of Europe and America."[25]

In his Saint Paul address of 1892, however, Osler repeated his contention: ". . . after all, the homœopaths only differ from the regulars in therapeutics. . . . And I do not differ more from my erring homœopathic brethren in the matter of therapeutics than I do from many of my regular brethren who write shot-gun prescriptions a yard long and fire them indiscriminately at their suffering patients."[43] He was quite willing that all candidates for licensure be subjected to the same examination in anatomy, physiology, surgery, obstetrics, pathology and practice, for "there is no homœopathic anatomy or physiology; no homœopathic surgery; no homœopathic midwifery; no homœopathic pathology; no homœopathic practice; there is only therapeutics of special difference."[43]

Osler's rather bizarre conception of the examining board for licensure in medicine never was accepted in the United States. By 1895—three years after he had spoken in Saint Paul—twenty-one states had the examination system for licensure, with the authority of the state government buttressing the examiners.[55] Fourteen other states would allow only graduates of accredited medical colleges to practice medicine. The "medical parliament" was nowhere in existence, nor, as Osler conceived it, does it exist in this country today. In medical licensure the authority of the state is supreme.

Yet Osler's preoccupation with medical licensure half a century ago should not obscure his real objective, which was of the utmost virtue and which has been largely attained today. For licensure in itself he probably cared very little. What vitally interested him was the improvement of medicine itself. If a physician could be licensed to practice medicine merely by the presentation of his diploma, then the medical college which had graduated him was, in effect, the licensing agent. Such a medical college might be a first-rate institution or a school of indifferent standards or even fraudulent conduct. A Philadelphia newspaper editor in 1880 encountered no difficulty whatever in purchasing two degrees of doctor of medicine, two doctorates in law, one degree of master of electrotherapeutics and one degree of doctor of sacred theology, from among six institutions duly incorporated by the state.[55]

If, on the other hand, the physician were required to undergo examination by the state, without regard to the institution from which he had received his diploma, then each school of medicine would be forced to offer instruction of such integrity that its graduates could reasonably expect to satisfy by examination any requirements a state licensing board might exact of them. Poor schools inevitably would decline; the quality of the training of the physician would improve; medicine itself would benefit immeasurably. This was Osler's primary concern. No one today can deny that it was eminently sound.

THE ROLE OF THE ELECTROCARDIOGRAM IN CARDIAC DISEASE

HARRY L. SMITH, M.D.

Rochester, Minnesota

ELECTROCARDIOGRAPHY has been used clinically for about fifty years. Its use stems back to the discovery that when a frog's heart contracts, it produces an electric current. For many years the electrical current of the hearts of animals was studied by use of a very crude apparatus. At first, the electrocardiogram was helpful clinically mainly in interpretation of cardiac arrhythmias. Great progress has been made in the mechanism and efficiency of the electrocardiograph, and greater progress has been made in the interpretation and clinical application of the electrocardiogram, especially in the past few years. Few fields of medicine have seen more noteworthy development than has electrocardiography.

Electrocardiography has developed to the point at which cardiac examination is not considered complete unless an electrocardiogram is made and, in the main, this is essentially the correct attitude. At times, the information furnished by an electrocardiogram is just as accurate and definite as that furnished by any known laboratory procedure. There are instances in which the electrocardiogram alone will enable the physician to make an accurate diagnosis. However, because of this fact, electrocardiography has been overemphasized and its use is often abused. Today, many electrocardiograph machines are in the hands of physicians who are not sufficiently trained to interpret electrocardiographic tracings correctly. Often, some insignificant changes in an electrocardiogram are incorrectly interpreted, and on this false basis alone a diagnosis of serious heart disease is made, with the result that the patient is needlessly condemned to a life of invalidism.

In the present era of mechanical efficiency, the unfortunate tendency among some physicians is to hope for an automatic mechanical method that will make the diagnosis without recourse to the standard and proved methods of examination. Dr. H. A. Wilmer's cartoon (Fig. 1) illustrates this point. This shows a physician who is too busy to obtain a history from the patient but who will make a diagnosis on the basis of the electrocardiogram alone—a very dangerous procedure. It is basically unsound and poor medicine for anyone to make clinical diagnoses on the basis of electrocardiograms alone.

"The doctor doesn't have time to take a history but he'll phone you the diagnosis tomorrow."

Fig. 1. A scene that is enacted too often in modern clinical medicine.

It should be remembered that the electrocardiogram is only a *report* of a laboratory procedure, and a very delicate procedure at that. The information derived in this manner should be used to supplement, and should be applied in conjunction with, information obtained from other sources, including (1) a carefully taken history, which is the most important part of the examination of patients who have coronary disease, (2) a thorough physical examination, (3) roentgenologic examination and (4) examination of the patient's blood. It should be realized that although the results of an electrocardiogram may be perfectly normal, the patient may still have very serious cardiac disease. A very important and practical test, and often a neglected one, is the amount of physical effort the heart can stand without the production of symptoms. It often is difficult for the physician to make a correct cardiac diagnosis, even when he utilizes the information gained from all available sources.

From the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

CHORIOEPITHELIOMA, MIXED MESODERMAL TUMOR, AND LEIOMYOSARCOMA OF THE UTERUS

Three Case Reports

HAROLD H. JOFFE, M.D., PHILIP F. ECKMAN, M.D., and ARTHUR H. WELLS, M.D.
Duluth, Minnesota

DR. A. H. WELLS: We wish to present the case studies of three patients with rare neoplasms of the uterus, with a concise review of each subject.

Chorioepithelioma

DR. P. F. ECKMAN: The patient (No. 34843) aged thirty-one, was admitted on November 10, 1945, in her first trimester of pregnancy, because of bleeding. Her first and second pregnancies in 1937 and 1942, respectively, were uneventful. She was treated with bed rest, sedation and progesterone. The bleeding ceased and she was discharged on November 25, only to be admitted a day later because of a recurrence of painless bleeding. The uterus was found to be firm, about the size of a three to three and one-half month pregnancy. The cervix was firm and closed. She was again treated conservatively, with cessation of bleeding, and discharged on December 3, 1945.

Three days later, on December 6, she was readmitted with bleeding and cramp-like pains. While in the hospital, two masses of placental tissue with grape-like refractile cystic protrusions were passed. Microscopic examination revealed swelling and hydroptic degeneration of the chorionic villi and large areas of necrosis, typical of a hydatidiform mole. There was no evidence of chorioepithelioma. A dilatation and curettage was done, which revealed no evidence of malignancy. The patient was discharged six days later on December 12, 1945.

The Friedman test, using 0.1 c.c. of urine, was positive on two occasions between her last discharge and readmission on January 15, 1946. A total hysterectomy was done on January 16.

Pathological Report

DR. A. H. WELLS: The uterus measured 11 by 7 by 5.5 centimeters. The outer surface was quite smooth, and the walls were slightly thickened. The endometrium was soft, gray and not unusually thick. There was a slight bulging of the endometrium in the fundus which was found to be due to an encapsulated, soft, gray, friable tumor mass in the myometrium, measuring 1 cm. in diameter and about 0.8 cm. below the endometrium (Fig. 1). No other tumor masses were noted, and the cervix was not unusual. Microscopic examination through this tumor nodule revealed large numbers of syncytial and decidual cells, both of which were embryonic in type with hyperchromatic and anaplastic nuclei, typical of a chorioepithelioma (Fig. 2). The lesion appeared to be fairly circumscribed, and no other malignant change was found in other parts of the uterus.

The patient was discharged on January 27. A Friedman test, at six months and at one year later, was negative. The patient, two years after her hysterectomy, is alive and well.

Discussion

DR. R. F. ECKMAN: Chorioepithelioma is a very definite and highly malignant disease entity, but is encountered with great infrequency. How rare it is may be inferred from the fact that during the thirty years following its original description by Stanger as a clinical entity, there were only 571 collected cases in the world literature. By a strange set of circumstances, it has fallen to my lot to attend two such cases. In reporting a case of chorioepithelioma of the uterus, Curtiss stated that he had seen only four other cases of proved chorioepithelioma of the uterus, all of which were studied only from pathologic aspects. In sixteen years of clinical experience he had seen but one case of chorioepithelioma diagnosed during life, although perhaps twenty patients with provisional diagnosis of this condition had been referred to him, in which the diagnosis was not confirmed.

In addition to the case which you have just heard reported, I would like to give briefly a case history of my other patient who was not as fortunate as was the one already described. This was a young woman, aged twenty-three, who was first seen in a rooming house about September 1, 1932, soon after a spontaneous delivery of a normal male baby at term. The delivery had been entirely unattended, and she had had no prenatal care whatever. After expressing the placenta, she was sent to St. Mary's Hospital, where her stay was prolonged to fourteen days because of some low grade fever.

When she presented herself for postpartum examination on October 3, 1932, a presumptive diagnosis of retained placental tissue was made, and she was returned to the hospital and curetted under anesthesia. A cosiderable amount of partially decomposed tissue was removed, which was reported by the pathologist as endometritis with decidua. She left the hospital five days later with the bleeding checked.

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota.

She remained quite symptom-free until the first part of January, when bleeding recurred. This was followed by fever, weight loss, and weakness. On pelvic examination the uterus was found to be enlarged and softened. She was readmitted to the hospital. The patient appeared obviously very septic, and a Friedman test was reported as positive. Because of the enlarging uterus, a positive Friedman test, and her septic condition, after consultation it was decided not to invade the uterus for diagnostic or therapeutic reasons at this time. Supportive and expectant treatment consisted of rest, fluids, blood transfusions, et cetera. During the next two months there was only partial abatement of her septic state, and during this time it became evident that the enlarging uterus was not keeping pace with that of a normal pregnancy. A Friedman test was again reported strongly positive. A histologic diagnosis of chorioepithelioma was established on endometrial curettings by the pathologist, Dr. George Berdez, on March 29, 1933. Exploratory operation and total hysterectomy was performed by Dr. W. A. Coventry on April 12. Due to the patient's poor general condition, death ensued within twenty-four hours. Examination of the specimen and autopsy revealed an invasive chorioepithelioma penetrating the uterus and invading the pelvic and iliac veins. Multiple emboli were found in the lungs, along with three metastatic nodules.

A comparative consideration of these two cases is most interesting from several points of view. One case followed labor at term and the other followed a hydatidiform mole. Polloson and Violet, in discussing the 455 cases in the literature in 1913, pointed out that 45 per cent of chorioepithelioma follow hydatid mole, whereas 21 per cent occur following labor at term. Another 30 per cent follow abortions, and 2.5 per cent occur after ectopic gestation. It has also been pointed out in the literature that a period of latency as long as three or four years has occurred following pregnancy.

These two cases illustrate very pointedly the difference in diagnostic approach and resultant handling because of development and better appreciation in the laboratory procedure. The quantitative fractional approach of the Ascheim-Zondek or Friedman test was not thought of in 1932 or 1933 at the time of this first case; in fact the positive Friedman test at that time served only to confuse the diagnosis in our minds by suggesting strongly the presence of another pregnancy as a threatened or probably incomplete septic abortion.

To approach the situation in the second case with the radical surgical procedure that had to be done, in the entire absence of all objective evidence of such a rare condition as chorioepithelioma, other than the evidence offered by a laboratory procedure, required much courage of one's convictions. The perfectly normal-appearing pelvis and uterus found upon opening the abdomen would cause some hesitation in going ahead with a total hysterectomy in this young woman. Only after finding this small malignant tumor entirely within the wall of the uterus did the futility of another diagnostic curettement appear evident, and such a procedure would only have served to confuse diagnosis further and increase indecision. Certainly in such cases, carefully controlled laboratory procedure may offer the only positive clue to the diagnosis and treatment.

Dr. H. H. Joffe: The etiology is obscure,[6,16] and the precursors may be full term pregnancy, abortion or hydatidiform mole,[1,6,10,14,16,20,25,30] as mentioned by Dr. Eckman.

Chorioepithelioma occurs almost entirely during the child-bearing period, in contradistinction to most of the other malignancies of the female genital tract.[6] In combining three series[6,20,30] totaling fifty-six chorioepitheliomas, forty-two (75 per cent) occurred in multiparous, and fourteen (25 per cent) occurred in primiparious women. The age in two series ranged from nineteen to thirty-nine[6] and seventeen to fifty-one[30] years.

To simplify the data on the precursors of chorioepithelioma, we have taken the liberty of combining five series[1,6,20,29,30] totaling 103 cases. In this combined group, sixty-three (61.1 per cent) followed hydatidiform moles; however, five were coexistant with the mole; twenty-three (22.4 per cent) followed abortion; ten (9.7 per cent) followed full term pregnancy, one of which was associated with pregnancy, and in seven (6.7 per cent) the precursor was unknown.

Hertig[14] found the ratio of hydatidiform moles to the number of deliveries to be 1 in 2,000. The ratio of chorioepithelioma to the number of obstetrical and gynecological patients varies with different series. Acosta[1] reports thirty-two cases of chorioepithelioma out of 21,765 obstetrical cases admitted to the Philippine General Hospital at Manila, or a ratio of one for every 680 obstetrical patients. A more detailed analysis revealed one chorioepithelioma for every 9.14 cases of mole, 474.44 cases of abortion and 4,563 cases of labor. Smith,[30] however, reports only fifteen cases out of a total of 117,260 obstetrical and gynecological cases admitted to the Charity Hospital at New Orleans, or a ratio of one chorioepithelioma in every 13,958 obstetrical and gynecological admissions. This closely parallels the report of Schumann[29] in which the ratio of chorioepithelioma in Philadelphia was roughly one to 13,847 pregnancies.

At this hospital over an eleven-year period, out of 12,722 patients delivered, there were eight (0.062 per cent) hydatidiform moles and one (0.0078 per cent) chorioepithelioma.

The early signs and symptoms are not characteristic and frequently resemble those associated with retained placenta, sepsis and involution.[6] The destruction of blood vessel walls by the invading anaplastic trophoblast elements produces the common and initial symptom of vaginal bleeding.[1,10,16,20,30] The bleeding may be irregular, sudden, severe or depleting.[6] In combining three series[6,29,30] totaling fifty-six in number, vaginal bleeding was the initial symptom in fifty (90.9 per cent) of the cases. Rosenbloom[27] reported a case of fatal intra-abdominal hemorrhage as the result of uterine rupture and extrusion of tumor tissue into the peritoneal cavity. Other symptoms and signs, such as nausea,

Fig. 1. Cut surface of chorioepithelioma is seen as a rounded dark lesion located 0.8 cm. below the endometrial surface or free margin.

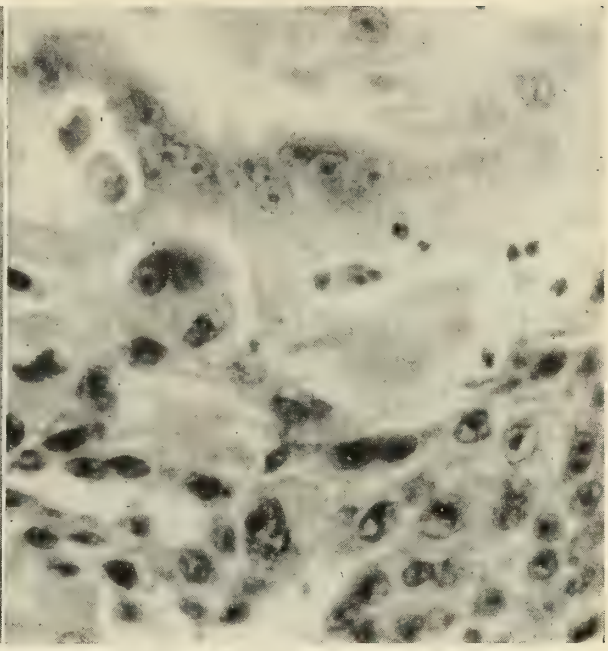

Fig. 2. Photomicrograph of anaplastic syncitial and Langerhan's cells of chorioepithelioma.

vomiting and enlarged uterus are encountered.[10,20,30] Pain is usually a late manifestation,[6] whereas, cough, chest pain, hemoptysis, headache and blurring of vision are indications of metastasis.[6,16] Bluish nodules in the vagina or vulva which ulcerate or bleed freely should arouse a high degree of suspicion.[16]

The early diagnosis of a hydatidiform mole cannot be overemphasized, but the immediate detection of a chorioepithelioma is of paramount importance. The diagnostic aids at our disposal are dilatation and curettage and the biologic hormone-urine tests. The diagnosis cannot always be established by a dilatation and curettage, because small growths or deep implantation can easily be missed.[16] The presence of anaplasia and invasion of Langhans and syncytial cells is diagnostic.

The urine in cases of hydatidiform mole and chorioepithelioma contains excessive amounts of gonadotrophic hormone which is the basis for the reaction in the biologic tests.[28] The qualitative and quantitative method have been used, however, the latter is a more reliable aid to early diagnosis.[25,28,30] Schoeneck[28] in order to secure normal standards as a basis for a quantitative test used the urine from 149 pregnant women in amounts varying from 0.0125 to 5.0 c.c. and determined the minimum amount necessary at various stages of normal intra-uterine pregnancy which would give a positive Friedman test. To avoid confusion and for practicability, the standards were expressed in terms of the actual amount of urine required and not the widely used terminology of the units of hormone per given amount of urine. In the absence of hyperemesis gravidarum and multiple pregnancy, a positive test was never obtained with amounts smaller than 0.05 c.c. Smith[30] likewise reports that a postive test with less than 0.05 c.c. of urine is indicative of a malignancy.

In one series[6] the average length of time between the occurrence of the precursor and the diagnosis of malignancy was nineteen months. In another series of forty-four collected cases[25] the interval between the passage of a mole and the diagnosis of chorioepithelioma varied from six days to five and one-half years. However, in the same series, in forty (91 per cent) of the cases the diagnosis was established by means of the biological hormone test within twelve months. The importance of monthly or trimonthly tests cannot be overemphasized. A single negative test does not justify its discontinuance.[25]

A positive biologic test for weeks after delivery of a full term pregnancy or following an abortion, or for six weeks or longer following the passage of an hydatidiform mole, is strong evidence of a malignancy.[6,25]

In thirty-six collected cases with recovery, the chorionic hormone test was negative in thirty-four (95 per cent) of the cases in less than three months and in twenty-four (66 per cent) in less than thirty days.[25]

The accepted method of treatment is a panhysterectomy; however, the removal of the primary tumor does not produce reabsorption of the metastases.[1] Dockerty[7] reported a case in which cerebral symptoms were the first indication of metastases, four years after the removal of the primary tumor. In one series,[1] twenty-one of thirty-two cases (62.5 per cent) showed metastases, of which eighteen (56.2 per cent) were to the lungs.

Mixed Mesodermal Tumor

Dr. F. D. Weeks: The patient (No. 41254) was first seen by me in October, 1931, at the age of forty-three because of scanty menstrual periods of several years duration and an associated bearing-down sensation. Physical examination revealed a moderate degree of arteriosclerosis with a blood pressure of 142/100. A large, tender, irregular shaped uterus was felt. A dilatation and curettage of the uterus was done, followed by the insertion of 50 milligrams of radium for twenty-four hours. A diagnosis of a papillary adenoma was made by the Department of Pathology of the University of Wisconsin.

A re-examination in June, 1932, showed a progression of the hypertension with a blood pressure of 186/118 and cardiac enlargement. There had been no further vaginal bleeding, and a pelvic examination revealed a small uterus with a slight enlargement at the right cornu. The cervix was not unusual. A pelvic examination about six months later, in December, 1932, revealed no change.

The patient was seen on many occasions during the next fifteen years. In October of 1947 she complained of lower abdominal discomfort. The blood pressure was 234/122, with albumin and casts in the urine. Pelvic examination showed no increase in the size of the uterus. She was again seen on December 26, 1947, at the age of fifty-nine because of vaginal bleeding of five days' duration after sixteen years of amenorrhea. Physical examination at this time revealed a blood pressure of 230/120. Urinalysis was essentially negative except for occasional granular casts. The red cell and white cell counts and hemoglobin were within normal limits. The uterus was found to be large, irregular, freely movable, but somewhat tender. There was a soft tumor mass extruding from the opened external os. On December 31, 1947, a supravaginal hysterectomy was performed. The tumor which projected through the external os was easily removed through the supravaginal procedure, leaving normal cervical tissue for closure.

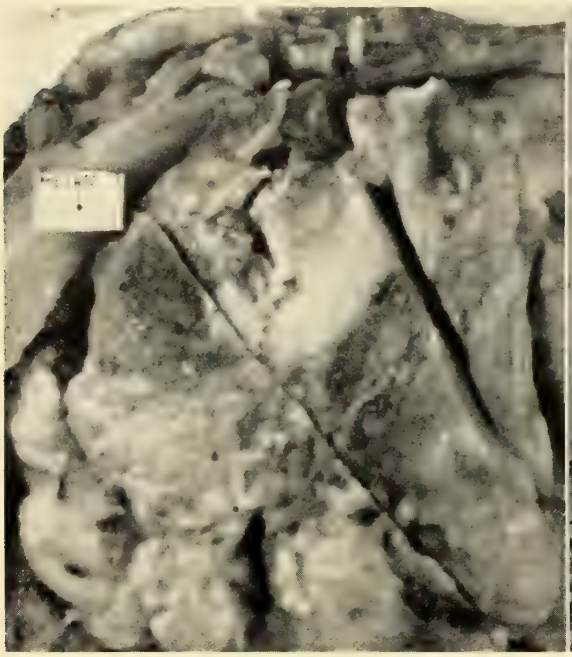

Fig. 3. Half of amputated fundus of uterus cut open exposing globular fibrous neoplasm (mixed mesodermal tumor) encased in thinned-out uterine walls.

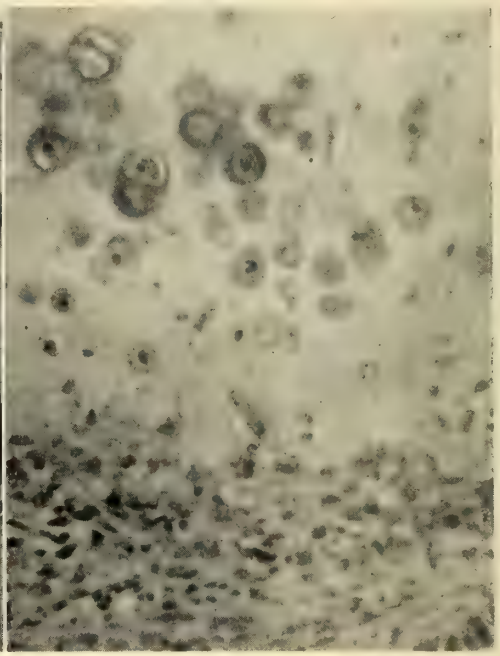

Fig. 4. Photomicrograph of area with cartilage cells and matrix.

Pathologic Report

Dr. A. H. Wells: The uterus measured 14.1 by 11.6 by 9.5 cm. The myometrium measured 1 cm. in thickness and formed a shell-like capsule incasing the nodular, grayish tumor mass measuring 13 by 10.5 by 8.5 cm. (Fig. 3). There were definite cystic areas in which the cysts measured from 1 mm. up to 0.4 cm. in diameter. Other areas of the tumor had a rather firm grayish homogenous surface. The center was soft and necrotic. Microscopic examination revealed anaplastic smooth muscle, fibrous connective tissue, cartilage (Fig. 4) and striated muscle cells, as well as columnar epithelial lined glands. In many areas there was marked anaplasia and in addition, large areas of necrosis, mitotic figures and tumor giant cells. A diagnosis of mixed mesodermal tumor of the uterus was made. No fallopian tubes or ovaries accompanied the specimen.

Discussion

Dr. H. H. Joffe: These tumors are of mesodermal origin, in contradistinction to the trigerminal teratomas. There is no unanimity as to their histogenesis. Whether they arise from Müllerian cell rests or tissue pulled

down by the Wolffian duct during its embryonic descent, is of academic interest.[12,17,18,22,23] The all-important feature is that these pleuripotential mesenchyme cells have retained their capacity to differentiate into a variety of mesodermal elements which are not normally found in the uterus, such as striated muscle, cartilage, bone myxomatous and sarcomatous tissue, et cetera. The stimulus to neoplasia and growth is unknown but is probably hormonal in nature.[22]

The tumor develops at one of three sites: corpus, cervix or vagina. Glass,[12] in reviewing ninety-four cases in the literature, found the corpus of the uterus as the primary site in 58 (61.7 per cent) and the cervix in thirty-six (38.3 per cent). Practically all of the corporal tumors occur after the menopause.[2,12]

The majority of the cervical tumors appear during active sexual life.[2,12] Amolsch[2] states that all reported cases of vaginal tumors occurred before the age of twenty-two years, with the majority occurring before the age of two years.

The tumors arising in the cervix appear as polyps and those in the corpus as massive intrauterine polypoid growths.[3,12] They are usually composed of a variety of mesodermal elements. Lebowich and Ehrlich[8,17] insist on the presence of embryonal myoblasts or striated muscle tissue in combination with one or more heterologous elements as the histologic criterion. On that basis they only accepted twelve cases as mixed mesodermal tumors in their review of the literature. It does seem unreasonable to exclude the majority of these tumors on such arbitrary histological criteria, since they are a distinct pathologic entity and all follow a rather typical clinical course.[22] Glass,[12] in reviewing ninety-four cases in the literature, found myxomatous tissue in twenty-seven out of thirty-six (75 per cent) tumors involving the cervix and in forty-one out of fifty-eight (70.7 per cent) involving the corpus. Cartilage was noted in 55.6 per cent of cervical, and in 60.3 per cent of corporal tumors. Striated muscle was found in 30.6 per cent of cervical, and in 41.4 per cent of corporal tumors. The stroma was composed of spindle cells in 75 per cent of cervical, and in 94.8 per cent of corporal tumors. Other mesodermal elements present were smooth muscle, bone, fat, round and giant cells in the stroma.

The symptoms and physical findings are essentially the same as with other malignancies of the uterus, namely, vaginal bleeding, saguino-purulent discharge and pressure symptoms if the mass is large or invades surrounding structures.[8,12,17,18,24] The diagnosis rests solely on the heterologous histologic picture and may be confused with a fibromyoma undergoing cartilagenous change or ossification, myosarcoma, rhabdomyoma, teratoma, carcinosarcoma, chondroma, myxochondrosarcoma and myoblastoma.[8] Carcinomatous degeneration is rare, however. Ehrlich[8] reported a case with superimposed adenocarcinoma, bringing the total of reported cases in the literature to fifteen. Glass[12] reported one case with associated fibroids, only eight such cases being previously described.

Local recurrence is almost a constant feature, and metastases to the vagina, bladder, parametria, broad ligaments, peritoneum, pleura, lungs and liver are common.[2,8,12] In a review,[12] metastases occurred in twenty-six out of thirty-six (72.2 per cent) cervical tumors, and in thirty-five out of fifty-eight (60.3 per cent) corporal tumors. Local recurrences occurred in 50 per cent of cervical, and in 27.6 per cent of corporal tumors. Although the lungs and pleurae are frequent distant sites for secondary growths, they rarely reproduce the parent tumor, but instead develop as a spindle cell or myxosarcoma.[12]

These neoplasms are malignant out of all proportions to their histological appearance, with a mortality of about 95 per cent regardless of therapy.[2,3,12,17,24] There are no five-year cures in the literature,[8] and the average duration of life following removal is about one year.[12]

The treatment consists of a panhysterectomy followed by irradiation, but then in view of the high mortality, is only a palliative measure.

Leiomyosarcoma

Dr. H. E. Bakkila: This fifty-eight-year-old housewife (No. 4016) was admitted to the hospital on February 20, 1948, complaining of a gradual increase in the size of the abdomen, an abdominal mass, a sensation of marked pelvic weight and a loss of 20 pounds since November, 1947. There was moderate anorexia, some recent urgency and questionable incontinence of urine. During the month prior to admission, there was increasing dyspnea.

Physical examination revealed a diffuse nontender enlargement of the lower abdomen which was firm and somewhat nodular. There was flatness to percussion, absence of ausculatory sounds, and no shift of the tumor mass with change of position. On pelvic examination the tumor mass was found to fill the entire pelvis with pressure on the uterus, vagina and rectum.

The urinalysis was essentially negative. The hemoglobin was 5.75 grams, with a red cell count of 2,190,000. The blood Kline test was 4-plus. A flat plate of the abdomen on February 21 led to the conclusion of intraperitoneal fluid or an intra-abdominal tumor. A chest film on February 26 was diagnosed metatastic lesions in the left lung.

The patient was prepared for operation with five blood transfusions, and on March 3, 1948, an exploratory laporotomy revealed a huge retroperitoneal mass rising out of the pelvis. A portion of the tumor mass had to be resected in order to close the abdominal wall. During the operation she received 1,000 c.c. of blood, but in spite of this her blood pressure gradually fell, and she expired approximately one hour later.

Pathologic Report

Dr. A. H. Wells: The necropsy revealed a huge nodular tumor mass weighing 6,000 grams, which formed a tight mold of the entire pelvis. The peritoneal cavity contained 2 liters of blood. The tumor mass extended mainly up the left side of the abdominal cavity to the diaphragm and displaced the abdominal viscera to the right. There were only traces of what appeared to be myometrium, visible in the form of strands separated

Fig. 5. A portion of cut surface of the leiomyosarcoma.

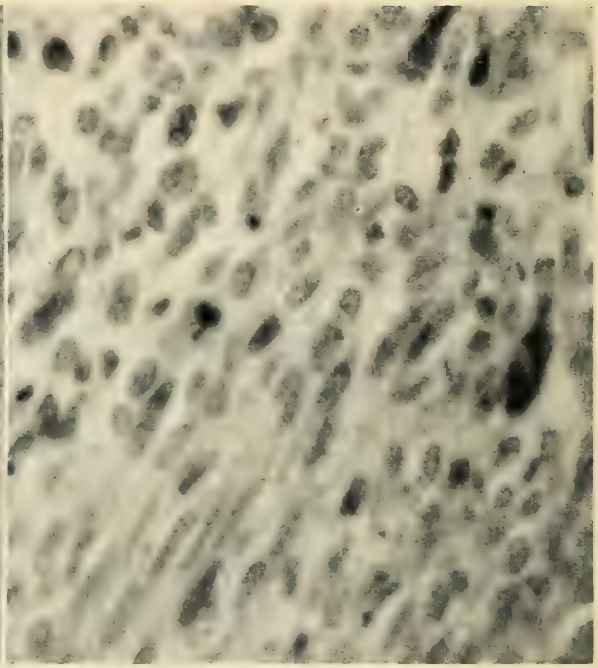

Fig. 6. Photomicrograph with anaplastic spindle cells, mitotic figures and tumor giant cells of leiomyosarcoma.

by tumor tissue. The cervix was not enlarged, and it blended with tumor tissue. Its os had disappeared. On cut section (Fig. 5) the nodules were made up primarily of homogeneous, rather firm, grayish tissue with extensive areas of cystic degeneration and occasional discrete yellow areas of necrosis measuring up to 6 cm. in diameter. Microscopic sections (Fig. 6) revealed a very highly anaplastic cellular growth, made up of elongated narrow nuclei with scanty cytoplasm streaming out at the poles. Where maturation could be found, the cells were typical smooth muscle in origin. Many mitotic figures and tumor giant cells were noted. Both lungs revealed typical metastatic tumor nodules, and both kidneys revealed a Grade I hydroureter and hydronephrosis. There was a Grade II syphilitic aortitis.

A diagnosis of leiomyosarcoma of the uterus with metastases to the lungs was made.

Discussion

Dr. H. H. Joffe: Leiomyosarcomas may originate in any part of the uterine wall, in the endometrium, adjacent connective tissue or in a leiomyoma, but they are commonly of myometrial origin.[4,5,24]

There is a diversity of opinion as to whether these tumors are malignant from their onset or whether the malignant change occurs in an originally benign tumor.[4,5,10,21,24]

Kimbrough[15] in reviewing 3,388 uteri removed for myomata found a total of forty-three (1.27 per cent) sarcomas, of which twenty-six (0.76 per cent) had developed in pre-existing leiomyomata and seventeen (0.51 per cent) were primary. Randall[26] found thirty-nine sarcomas against 3,686 leiomyomas and 577 carcinomas of the uterus. Of the thirty-nine sarcomas, twelve (0.32 per cent) were associated with myomas, and twenty-seven (0.73 per cent) occurred in uteri showing no leiomyomata. The ratio of leiomyosarcoma to carcinoma was one to 15.6, and one to ninety-six for leiomyomata. Other reports place the ratio of leiomyosarcoma to carcinoma as one to forty-three[32] and one to fifty.[5] Novak,[24] in reviewing 26,973 case specimens of uteri, found 6,981 (25.9 per cent) leiomyomata, 241 (0.89 per cent) adenocarcinomas of the fundus, 1022 (3.8 per cent) carcinomas of the cervix, and 59 (0.22 per cent) sarcomas. The incidence of sarcomatous change occurring in myomas was 0.56 per cent. Other series show a higher incidence of sarcomatous change in pre-existing leiomyoma, varying from 1.35[33] up to 4.8[11] per cent. A fair average would probably fall between 0.5 to 1.5 per cent.[4,21,24]

During the eleven-year period from 1937 through 1947, 816 uteri were removed at St. Luke's Hospital for leiomyomata. In this group, three (0.36 per cent) were sarcomatous. Although this series is too small to draw any definite conclusions, the incidence at this hospital closely parallels the figures reported in some of the larger series.

The majority of these tumors occur at menopause with the highest incidence during the fifth decade of life.[10,11,15,24,31]

Mural sarcoma may arise as a nodular and fairly circumscribed tumor,[24] and since they vary greatly in their appearance, it is difficult to recognize them.[11,24] However, because of the frequency of leiomyomata uteri, there is a tendency on the part of surgeons to

be careless in their examination at the time of surgery.[31]

The more frequent occurrence of corporal than cervical leiomyoma explains in part at least, the predelection of sarcoma for the corpus of the uterus.[24]

The sarcomatous changes occur most frequently near the center of the myoma, giving it a raw pork or brain-like appearance instead of the glistening whorl like nature of a myoma.[24,32] Wheelock[33] states that the following findings at the time of surgery should arouse suspicion of a sarcoma in a leiomyoma:

1. Unusual friability of the broad ligament.
2. Unusual vascularity of the tumor.
3. The absence of a sharp line of demarcation between the tumor and the myometrium.
4. The opaque pork or brain-like appearance instead of the usual glistening whorl-like appearance.

The microscopic picture is characteristic of sarcomas, that is, highly cellular with wide variations in the predominate type of cell present, which may be round, spindle, mixed or giant cells.[11,21,24] Many observers feel that there is a direct correlation between the number of mitotic figures and the degree of clinical malignancy.[4,9,15,24]

Th clinical symptoms are not distinctive and resemble ordinary leiomyomata, so that most of the cases are not diagnosed until examined pathologically.[9,21,24] In a review of forty-three cases at the Lahey Clinic,[31] the chief complaints were: altered menses in twenty-one (49 per cent), pelvic pain and enlarging abdomen in nine each (21 per cent), urinary frequency in eight (19 per cent), and vaginal discharge in two (5 per cent) of cases. Abnormal bleeding may be entirely absent, especially if the endometrium is not involved. The vaginal discharge, early, is thin and watery; later it becomes serosanguinous and foul. Pain is a late manifestation of infiltration into adjacent tissue.[24]

The total five-year salvage in forty-three sarcomas at the University of Pennsylvania Hospital[15] was 34.3 per cent, as compared to 28.5 per cent in another series.[31] Novak[24] followed fifty out of fifty-nine cases and found fifteen (30 per cent) living at the end of fifteen years, and twelve (24 per cent) at the end of ten years. Kimbrough[15] found that the percentage of five-year cures were: (1) three times as great in sarcomatous degeneration of a myoma than in a primary sarcoma, (2) three times greater in the younger women as compared to those operated on after menopause, (3) four times greater in those tumors showing a low mitotic count, with recurrences, two times as frequent in the group showing a large number of mitotic figures.

Metastasis to distant organs, although not too frequent, do occur.[10,13] However, metastasis to bone is extremely rare, with Brooke[4] reporting the fourth such case.

Panhysterectomy with bilateral salpingo-oophorectomy, followed by deep x-ray therapy, is the accepted form of treatment.

Summary

We have presented a case study of each rare neoplasm of the uterus—(1) chorioepithelioma, (2) mixed mesodermal sarcoma, and (3) leiomyosarcoma— and have given a brief review of the literature on each subject.

History of Medicine In Minnesota

A HISTORY OF MEDICINE IN SCOTT AND CARVER COUNTIES

Biographical Dictionary

(Continued from June issue.)

George F. Mish was a physician and surgeon who settled in Belle Plaine, Scott County, in the year 1858. He remained but a short time.

L. Gilbert Mitchell settled in Carver County about 1886. He lived first in Waconia, then moved to Jordan, Scott County, in 1890. He was well liked there and gained an extensive practice in Jordan and the vicinity. During this time he made connections in Shakopee, and in 1893 he located there to take Dr. Entrup's place after the latter's death. He remained there for several years, then moved to Mound. During his stay in this territory, he acted in the capacity of health officer of Waconia during a dangerous scarlet fever epidemic in 1887, and also served as treasurer of the pension examining board at Shakopee. He was the son of Dr. S. H. Mitchell of Minneapolis.

Gerald R. Moloney was born in 1847 in Ireland, where he attended the national schools and completed his course of studies in Dublin. In December, 1872, he arrived at Belle Plaine, Scott County, and early the next year he went to Minneapolis. There he studied medicine under Dr. Hutchinson until the following autumn, when he attended lectures at Bellevue Hospital Medical College, New York City. The next summer he studied in Saint Paul under Dr. C. E. Smith, and in the fall returned again to New York, graduating in February, 1875, from the Medical Department of the University of the City of New York. He was a successful competitor in an examination at St. Vincent's Hospital of New York and was duly appointed assistant house surgeon. In the fall of 1875 he opened an office at Belle Plaine, Scott County, where he remained for more than fifty years and where in 1877, he opened a drug store. He had a very extensive practice and became one of the prominent businessmen of the town as well as one of the county's leading physicians. One of his first services in public office was in the capacity of superintendent of schools in Belle Plaine. For many years he served on the pension examining board at Shakopee, serving as president for the year 1883 to 1884. He was succeeded by Dr. Hartley in 1897. In the year 1900, Dr. Moloney and G. A. DuToit of Chaska purchased all the stock in the State Bank of Belle Plaine and Dr. Moloney was made vice president. He continued to practice medicine at Belle Plaine until his death, on July 18, 1927, in an automobile accident.

L. B. Morrow came to Shakopee to practice medicine in 1867. He was at first a partner of Dr. Rouse. After a few months Dr. Rouse moved into the house formerly occupied by Dr. Risley and had his office there. Dr. Morrow had taken over the New Drug Store, which he operated for a short time in

connection with his practice. He remained in Shakopee for several years. At one time he practiced in Hudson, Wisconsin, and also in Saint Paul. He died in Saint Paul.

J. F. Mulholland came to Jordan, Scott County, in 1881 and was, for the first two months of his residence, a partner of Dr. Walter of that town. Dr. Mulholland was a graduate of the Chicago Medical College in 1879 and was an intern in the Mercy Hospital of Chicago. Not long after his arrival in Jordan there was a severe scourge of diphtheria in the county and he and Dr. Walter were kept busy attending the sick. In February, 1882, he was appointed surgeon for that division by the Minneapolis and St. Louis Railway Company. He was active in local affairs to the extent of speaking before such organizations as the Literary Society and the Teachers Association. In 1895 he was appointed to the pension examining board in Shakopee. He died in Jordan on August 23, 1919.

Andrew Naegeli was graduated from the Medical College of Indiana in 1885 and he settled in Chaska in 1886. His card announced, "Night and day calls in the city or country promptly attended to," and he built up a good practice after a short time. In 1890 he moved to Minneapolis to take the place of Dr. Hefti. After a year's stay there, he went to St. Cloud, but in 1898 he again came into the Minnesota Valley region and located at Hutchinson.

S. J. Northrop came to Jordan, Scott County, about 1870 from which place he had a wide practice in both Scott and Carver Counties. About 1882 he moved to Norwood, Carver County. At that time he met a considerable amount of disfavor by putting his mother in the St. Peter Asylum. He continued to practice in Carver County for a number of years. He probably was not a graduate of a medical school, inasmuch as he practiced under the exemption law of 1883.

Edward E. Novak was born at Danforth, Johnson County, Iowa, on April 29, 1873. He was educated in the rural schools of Johnson County and attended the Iowa City Academy from 1888 to 1892. He was graduated from the Medical Department of the State University of Iowa in 1895.

After his graduation he located in New Prague where he has continued in practice to the present time, with the exception of two six-month leaves (1912 and 1932) when he visited European clinics. He is a member of the Scott-Carver County Medical Society and the Minnesota State and American Medical Associations.

Always interested in rural education problems, he has served on the New Prague School Board for over thirty years. He was president of the Minnesota State School Board Association from 1937 to 1938 and he is now a member of the Board of Regents of the University of Minnesota. In recent years he has served as Minnesota state senator from his district.

Gottlieb Oppliger settled in Waconia in 1899. Before 1909 he was in Baudette, Minnesota.

George H. Overholt, a graduate of the Albany Medical College, New York, in 1866, located at Shakopee, Scott County, in January, 1871. His card announced him as "Physician, Surgeon, and Obstetrician." After practicing at

Shakopee for two years or more, he moved to St. James, where he lived for many years and operated a drug store. He was licensed to practice in Minnesota in 1887.

E. J. Palmer, a graduate of the University of Pennsylvania, came to Chaska in 1869 and at that time said that he had spent thirty-one years in the practice of his profession. He remained only a year, returning then to his old home in Georgia.

John S. Pashley located in Belle Plaine, Scott County, about 1866. He practiced there until his death in 1876.

W. H. Phillips was a graduate in medicine from the University of Minnesota in 1894. He came to Jordan to practice about 1896 and remained in the county many years. He served as county physician in 1897.

William Ray was a graduate of the Missouri Medical College in 1868, who came from St. Louis to Chaska in that year and remained in practice there about five months. For a short time he practiced in Saint Paul, and in September, 1868, he moved to Glasgow, Missouri, a larger field for practice.

H. W. Reiter was graduated from the Medical Department of the University of Minnesota in 1893. Practicing first in Kerkhoven, Swift County, he settled in Shakopee in 1897 and soon had a good practice. He was very often summoned to attend accident cases. In 1898 he was appointed official surgeon of the Omaha Railway at Shakopee, a position which he has held for many years. On the departure of Dr. C. W. Malchow in 1900, Dr. Reiter purchased the former's practice, office equipment, horses and vehicles. He had a heavy practice which kept him busy, and he retained his prominent position. In 1910 he became United States pension examiner at Shakopee and served as secretary of the board. In 1914 he took office as coroner of Scott County; he served on the school board four terms. Dr. Reiter joined the Scott and Carver County Medical Society when it was first organized, and he held the secretaryship from 1904 to 1929.

Dr. Rueten was a practicing physician at Cologne in 1886.

J. S. Richardson (or J. L. Richardson) came to Chaska from Rockford, Wright County, in 1870. His professional card read:

> Dr. J. S. Richardson
> eclectic
> Physician and Surgeon
> Chaska Minn.
> Office opposite the Court House. Offers his services to the surrounding country and is prepared to treat thoroughly all chronic cases.' Especially liver and lung diseases.

He remained in Chaska for several years. Later he may have moved to Norwood, where a doctor was much needed. After 1883 he practiced under an exemption certificate. It appears that by 1890 he was in Perham, Otter Tail County.

C. W. Riches practiced medicine in Waconia in 1886 and later. In 1883, when he was living in Young America, he received an exemption certificate under the Minnesota "Diploma Law" of that year.

Frederic N. Ripley, the first physician in Scott County, arrived in Shakopee in the winter of 1852-1853 and in that season entered business and practiced medicine. Although he failed in trade, he continued practicing medicine there. Later in the year 1855 he moved to a townsite belonging to him near the source of the Crow River (now the town of Litchfield), where he camped all winter. When in March he attempted to come out for supplies, he lost his way and was frozen to death. At that time he was about twenty-eight years of age, and was county commissioner of the new county of Meeker. He had intended to make Cedar City his home and was one of the principal proprietors of that town. Dr. Ripley was a native of New York.

A. O. Risley came to Shakopee in 1855 and practiced there for ten years or more. He was a member of the North Western Pioneer Company and he made many trips around the territory procuring and surveying town sites. In 1857 he married Miss S. J. Coulthard of Shakopee. He was one of the few physicians in the vicinity at that time and consequently was kept busy day and night when any sickness came to the community.

Theobold Roehrig was a German physician who settled in Shakopee in 1868. The notice of his coming inserted in the paper announced that he was a graduate of the "highest Medical University of Germany," and that he brought with him the advantages of many years of successful practice. He remained three years or more.

Corydon Eugene Rogers was graduated from the medical department of the University of New York City in 1868. He opened an office in Carver in April, 1868, and soon had a good practice. For several years he was postmaster at Carver. In 1869 he married Miss Mary Pamelia of Troy, New York. In January, 1870, he was appointed first county physician of Carver County. He resigned the position in August of that year when he decided to move to Thompson, on the line of the Superior Railroad, in Carlton County. He was elected register of deeds for that county, but continued to practice medicine. Four years later he went to Minneapolis where he engaged in the insurance and real estate business. In Minneapolis on November 10, 1883, he received his license to practice medicine.

William Rottmann was graduated from the University of Zurich, Switzerland, in 1874; he came to Jordan, Scott County, from Arlington in September, 1883. His card read:

Dr. Wm. Rottmann
Physician & Surgeon
(Deutscher Arzt)
Graduated in Zurich, 1874
Jordan, Minn.

He received his license to practice medicine in Minnesota on March 3, 1884. After a year or two he moved to Young America and then returned to Jordan about 1888. In May, 1889, he again changed his place of residence

and moved to Minneapolis. He was considered a skillful physician. In September, 1889, he died at Minneapolis.

Dr. Rouse settled in Shakopee about 1858. He practiced medicine there for ten years or more. In 1867 he took in Dr. Morrow as a partner.

B. Rudorf was a practicing physician in Young America in 1875.

Jacob Ryder settled in Cologne, Carver County, about 1884. He was interested in real estate and for that reason he moved to Saint Paul in 1887. In 1890 he lived in Albany, Stearns County, and late in that year he returned to Cologne. He was considered an able physician. After 1883 he practiced under Exemption Certificate No. 417-3.

Alfred A. Sabin established himself in Shakopee in 1883. He and his wife were active in social affairs and he had a good practice. He started the manufacture of a patent medicine and in 1885 the demand for it had reached large proportions. In 1886 he moved to Le Sueur, where he remained until 1892, returning at that time to Shakopee to take Dr. J. B. Dunn's place. In 1894 he was appointed city health officer, and the next year he was elected to the pension examining board at Shakopee. He had a wide acquaintance in both Carver and Scott Counties and practiced in both. He died at Shakopee after a seige of muscular rheumatism in February, 1896, at the age of forty years. He was a native of Indiana and had spent his boyhood in Michigan, moving to Minnesota in 1879. He received his medical education at the University of Minnesota, from which he was graduated in 1892.

Mrs. Catherine Salden was a practicing physician who claimed to have been licensed by the United States Government. She spent a brief time in Chaska in 1870.

Dr. Salisbury was the first physician in the township of St. Lawrence, Scott County. He came there in 1859 and remained but a short time. A schoolhouse was built in 1859 and Dr. Salisbury taught the first school held there.

M. Schober came to Chaska from La Crosse in February, 1899. He had been a member of a medical society in Wisconsin. His professional card entered in the *Valley Herald* read as follows:

Dr. M. Schober
of the University of Berlin
Physician and Surgeon
Special attention given to all surgical
diseases and diseases of the eye.
Office Starken Building

He was a skillful and popular surgeon who endeavored to interest the citizens of Chaska in a project he had for the equipping of a first-class hospital in the city. In June, 1900, he had succeeded in securing the co-operation of the Franciscan Brotherhood of Chaska and the surrounding stations, and was awaiting the sanction of Archbishop Ireland for the venture. There was no hospital in either Scott or Carver County at that time.

Edward A. Shannon was graduated from the Saint Paul Medical College in 1886. In 1888 he established his residence at Watertown, Carver County, where he served as coroner in 1891 and 1892. He moved away from the county in 1892, later locating at Buffalo, Wright County.

Peter F. Shillock was born in New Ulm, Minnesota, in 1858. He was graduated from the medical department of the University of New York City in 1882, ranking second in a class of two hundred. When he received his Minnesota license on November 23, 1883, he was living in Hastings. Later he began practicing in Chaska and became well known through Carver County. After three or more years of practice there, he moved to Horicon, Wisconsin. Later he returned to Hastings. He died in Hastings of apoplexy in November, 1888, at the age of thirty.

E. E. Shrader (or Shroeder), who was graduated from Jefferson Medical College in 1893, located at Watertown, Carver County, about 1895. He soon had a very good practice there which drew from the towns of that vicinity.

J. D. Simpson, a graduate of the Medical College of Chicago in 1881, came to Shakopee early in that year. In May of the same year he moved to Henderson, Nicollet County. Soon after that he married Miss Sarah Lord of Shakopee. Dr. Simpson spent the year 1893 in New York and the following year in study in the hospitals of England where he specialized in diseases of the eye. In July, 1894, he settled in Minneapolis, where he practiced for a number of years, although he continued to keep up his contacts with the people of Shakopee.

Herbert O. Smith was a homeopathic physician who was graduated from Hahnemann Medical College, Chicago, in 1881. Before coming to Shakopee in June, 1881, he spent some time as a student of Dr. John A. Steel of Minneapolis. His card read:

H. O. Smith, M.D.
Physician & Surgeon
Shakopee, Minnesota
All cases of Surgery or General Practice in town or country attended promptly. Office over McMullen's store. Residence 1st door east of Occidental hotel.

Office hours 10 to 12 a.m.
2 to 4 p.m.
7 to 8 p.m.

He soon became one of the best known and busiest doctors in the county. He had a famous team of horses which brought him to each call in the minimum of time. Evidently he prospered; his home was spoken of as one of the most imposing in town and it was constantly being improved. He took frequent trips to Minneapolis and Saint Paul and had many house guests. Dr. and Mrs. Smith were very active in organizational work. The doctor was interested in the Shakopee Equitable Aid Union and held many offices in that society; he also held offices in the E.A.U., in the King Solomon Lodge No. 44, A. F. & A. M., in the A.O.U.W., in the Children's Home Society, the St. John's chapter of the Royal Arch Masons, and the Masonic Auxiliary in Shakopee. For several years he served as city health officer in Shakopee, also as county physician, and was for many years a member of the pension

examining board. He also took an active interest in the schools and in the building of the new Presbyterian church in 1900.

John Elfred Soper, who was graduated from the University of Minnesota Medical School in 1894, came to Norwood, Carver County, in January, 1899, after the death of Dr. Koch of Norwood. He had previously practiced at Delano.

Dr. Southworth came to Belle Plaine in the middle fifties. In 1861 he was elected a director of the Scott County Agricultural Society.

Hugo Speier, who had been educated in medicine in Berlin, Germany, settled in Belle Plaine about 1883 and married there. He was licensed to **practice medicine** in Minnesota on December 31, 1883, and was graduated from the College of Medicine of the University of Minnesota in May, 1884. In July, 1884, he settled in Jordan, where he shared offices with Dr. Walter. His professional card read:

Dr. H. Speier
Physician & Surgeon
(Deutscher Arzt)
Office with Dr. Walter
Residence in F. Nicolin's building, at south
end of stone bridge.
Jordan, Minn.

Beginning in February, 1901, Dr. Speier was in Rochester, Minnesota, about ten years. He came to Rochester from Janesville, Wisconsin, with a record of having practiced medicine in Duluth some fourteen years and in Janesville four years.

C. S. Stoddard started the practice of his profession at Shakopee in 1874. During his stay of five years in Shakopee he held offices in the Lodge of Good Templars at Shakopee, and in the Grand Army of the Republic of Minnesota. In 1875 he was appointed United States examining surgeon for pensioners of Scott County. In 1879 he moved to California where he practiced for many years. In 1900, while in Santa Barbara, California, he wrote a series of articles called "Looking Backward" which told of his experiences in Shakopee during the seventies. These were published in the *Scott County Argus* in that year.

W. Strickland came from Shell Rock, Iowa, to Jordan, Scott County, in July, 1879. He decided not to stay and left in search of a new location in August of that year.

F. H. Stuart opened an office in Shakopee for the practice of medicine and surgery in October, 1879. He worked up a fine practice, then suddenly left. He next settled at Ada, Kittson County, where he became notorious, first leaving under a cloud, then returning, only to disgrace himself by killing another physician in a fight in 1885.

L. S. Thompson located in Shakopee in March, 1874. In his card he referred by request to Drs. Murphy, Hagan, Richeson and Stone of Saint Paul. He arrived soon after Dr. Stoddard and proved an energetic rival. In April he was selected by the pension department to fill the vacancy made by the death of Dr. Wakefield as United States examining surgeon for Scott County.

After remaining about one year in Shakopee, he moved to Honolulu where he engaged in raising sugar cane.

E. L. Thorp, "physician, surgeon, and accoucheur," located at Jordan in March, 1879, but departed in a few months to practice medicine at Shell Rock., Iowa.

C. F. Tuomy, who received his degree of doctor of medicine from the University of Michigan in 1896, arrived in Chaska in January, 1897, and soon came to the front as a successful practitioner. In April, 1898, he was elected to serve for three years on the Chaska board of health. In September of that year he was elected to fill the position of assistant physician at the state hospital at St. Peter.

Dirk Van Krevelin came from Hokah, Houston County, to Belle Plaine in 1879. He announced that he had had a large experience in the tropics and malarial districts, on shipboard, and in marine and naval hospitals. In 1880 he served as coroner of Scott County. He was considered both honest and genial and he had a good following. In 1888 he bought the store of R. Zeglin, a well known merchant at Hollywood, a town near New Germany, Carver County. It was a general merchandise store, and the doctor added a hardware store to it. The next year he sold out at cost, having decided to give up the merchandising business. He then settled at Waconia, where he practiced medicine until 1897 when he moved with his family to Silver Lake, McLeod County.*

Dr. Van Pol practiced near Benton, Carver County, about 1886. He died in 1888 and was buried from the Catholic church at Cologne.

A. Wagner was graduated from the University of Berlin (University of King Frederick Wilhelm) in 1873. He was a specialist in diseases of women. In June, 1887, he came from Joliet, Illinois, where he was physician for St. Joseph Hospital, to locate at Waconia. He was successful there and in the nearby towns. In November of that year he moved to Chaska. Three months later, he moved to Saint Paul where he was associated with Dr. A. J. Stone in the Saint Paul Medical College.

John L. Wakefield was born in Winsted, Connecticut, in 1823. He was graduated at Yale College in 1847 and commenced the practice of medicine under the direction of his father at Winsted. He came to Shakopee in the spring of 1854, and practiced there until his death in 1874, at the age of fifty-one years.

In 1862, at the time of the Indian outbreak, Dr. Wakefield was physician to the Yellow Medicine Indian Agency. The doctor escaped, but members of his family were captured by the Indians and held for six weeks until recaptured by the troops. Dr. Wakefield became postmaster in Shakopee in 1869. At the time of his death he had a very extensive practice and was one of the prominent citizens of that vicinity.

A. B. Walter was among those who made claims in 1854 in Belle Plaine, although he did not reside in that village or practice medicine there until 1860. After five or six years in Belle Plaine, he sold his claim and moved to Jordan, also in Scott County.

Dr. Walter was one of the best and most popular physicians in the county.

*See Notes on History of Medicine in Houston County.

About 1879 he and Dr. F. W. Cram formed a co-partnership, and the two physicians paid daily visits to Belle Plaine, and attended many patients in the country as well. In 1881 Dr. Cram departed, and Dr. Walter continued to practice in Jordan until 1887, when he moved to Minneapolis. In the winter of 1888-1889, Dr. and Mrs. Walter lived in Shakopee with their daughter, Mrs. Southworth. The Scott County Medical Society was formed about that time (1887) and Dr. Walter became a member. He next moved to Princeton, Minnesota, where he remained until 1897. At that time he and Mrs. Walter moved to Sheldon, Iowa, to live with their son-in-law, Dr. F. W. Cram and his two children. Dr. Walter died there at the age of eighty years in 1898.

Josiah S. Weiser, of German descent, was a native of Berks county, Pennsylvania. He came with his parents and two brothers to Minnesota in 1853. His father died from cholera on the Mississippi River boat on which they finished the journey, and was buried at Saint Paul.

Dr. Weiser settled in Shakopee about June, 1855, and his professional card appeared in the first issue of the *Shakopee Independent.* In April, 1856, he entered into a co-partnership with Dr. C. L. Davenport. This was dissolved by mutual consent a few months later. In 1859, when Dr. Weiser became the partner of David L. How, druggist and chemist, he continued to attend to the practice of medicine and surgery. He was interested in public affairs and often took part in debates and discussions. Dr. Weiser was well liked and respected by the settlers in Shakopee; in 1858 he was elected mayor of the city.

In 1862 when he received appointment as Surgeon to the First Regiment of Mounted Rangers under Colonel McPhail, the women of Shakopee made him a present of a sword and a belt. It was in the outbreak of the Sioux during the next year that he met his death at the age of thirty years. An account of his heroism may be found in the records of the Sioux outbreak. Suffice it to say he is ranked among the heroes of pioneer days who were members of the medical profession. Ten miles north of Tappan, Minnesota, there is today a gray granite marker bearing the legend:

Sibley Trail
Dr. J. S. Weiser Shot Here
By Indians
July 24, 1863

K. B. Wilkinson was a physician and surgeon who located at Jordan in August, 1876. His stay was of short duration.

Phillip M. Williams was a physician and surgeon who located at Belle Plaine in March, 1858. The following quotation from the *Belle Plaine Enquirer* for May 13, 1858, is not too flowery to indicate the place Dr. Williams held in the community:

Our Citizens are sorry to learn that Doct. Williams leaves Belle Plaine for another field of professional practice. It was not indeed expected that a physician of his acquirement and thorough training could long be retained in a comparatively new region when there were so many larger and more congenial fields for the display of medical skill in the older cities of the country.

Dr. Williams had been in Belle Plaine less than one year and yet he had acquired a widely extended business and to our knowledge had also given the highest satisfaction.

Equally popular and respected in social as in professional life is Doct. Williams, for our friend is a gentleman as are all the Virginians in Belle Plaine.

President's Letter

THE BROOKINGS REPORT

One of the most significant books to be published recently—and one which will certainly come as "good news" to physicians—is a small volume entitled "The Issue of Compulsory Health Insurance." This book, an impartial and unemotional presentation of *facts,* not propaganda, is the work of a research agency famous for its work in the social sciences, the Brookings Institution of Washington, D. C.

Every physician will want to read this book, for its contents are indeed heartening—as well as enlightening. In fact, every thinking American should become familiar with it. It is a very unimposing volume, bound in a modest blue cover, but in its pages are some of the most cogent arguments in behalf of the voluntary system of providing for medical care yet to be advanced.

The evidence against compulsory health insurance is conclusive. In the opinion of the Brookings experts, it would be unwise to legislate, in place of the present system, a federalized medical care plan. Such a plan, they hold, would be distinctly detrimental to medical progress.

The Brookings report is the work of two of the Institution's senior staff members, Drs. Lewis Meriam and George W. Bachman, both of whom are familiar with government service, medical research and public health. They have examined all of the literature in the field and have carefully evaluated all of the evidence; the result proves definitely that traditional American methods are superior to foreign ideologies.

All things considered—American death rate, life expectancy, medical costs, capacity to pay, and all the rest of the factors that must be fitted into the American health picture—the Brookings report concludes that the present system is basically sound. Certain arguments often used in support of compulsory measures are effectively refuted, for example, the "draft statistics." It is shown that the so-called draft statistics are unreliable as a measure of the health of this nation and cannot be used to show medical needs.

Another striking point made by the Brookings report is one which physicians have argued for some time: that people won't be any more able to pay a health tax than they are able to budget for medical bills on a voluntary basis. It is also pointed out that there aren't enough facilities, trained workers and qualified professionals to carry out a compulsory health program should one be instituted.

The Brookings report has been made upon request of Senator H. Alexander Smith, chairman of the subcommittee on health of the Senate Committee on Labor and Public Welfare, which is charged with the duty of evaluating proposed federal health legislation. Senator Smith asked specifically that the Brookings Institution evaluate the relative merits of two bills which have been pending before the Eightieth Congress, S. 1320 (paralleling the Wagner-Murray-Dingell Bills) and S. 545, the Taft-Smith-Ball-Donnell Bill.

The proposal labelled S. 1320, which is in essence a bill to create an over-all federal health plan, is not recommended by the Brookings report. The report favors, rather, the other measure, which would provide federal grants-in-aid to states so that each individual state could develop its own plan adapted to fit local needs.

The fact that the Brookings Institution is recognized as a thoroughly independent organization only serves to increase the indebtedness of the medical profession to it for the excellence of this objective piece of work. It should spur the effort of physicians everywhere to fight even more vigorously for what we *believe* is right and what has been *proved* to be the better course.

President, Minnesota State Medical Association

THE STATE MEDICAL MEETING, 1948

THE ninety-fifth annual meeting of the Minnesota State Medical Association which was held in Minneapolis, June 6-9, was the largest in registration in history. Some 1,989 physicians, 768 nurses, 525 exhibitors, 349 Woman's Auxiliary members, and 609 guests attended. The 1949 meeting will be held in Saint Paul.

The following officers for 1949 were elected:

President-elect: Ernest M. Hammes, M.D., Saint Paul (takes office as president, January 1, 1949)
First Vice President: C. E. Proshek, M.D., Minneapolis
Second Vice President: A. E. Sohmer, M.D., Manakto
Secretary: B. B. Souster, M.D., Saint Paul (re-elected)
Treasurer: W. H. Condit, M.D., Minneapolis (re-elected)
Speaker of the House of Delegates: Charles G. Sheppard, M.D., Hutchinson (re-elected)
Vice Speaker of House: Haddon M. Carryer, M.D., Rochester (re-elected)
Councilors:
Fifth District: Justus Ohage, M.D., Saint Paul (to replace Dr. E. M. Hammes)
Fourth District: H. J. Nilson, North Mankato (succeeding Dr. Sohmer)
Sixth District: O. J. Campbell, M.D., Minneapolis (re-elected)
Eighth District: W. L. Burnap, M.D., Fergus Falls (re-elected)

Delegates to the American Medical Association:
J. A. Bargen, M.D., Rochester (succeeding Dr. A. W. Adson)
W. A. Coventry, M.D., Duluth (re-elected)

Alternate delegate to the American Medical Association:
J. C. Hultkrans, M.D., Minneapolis (re-elected)
W. L. Burnap, M.D., Fergus Falls (re-elected)

On Sunday afternoon, Dr. Ludwig L. Sogge of Windom received a special citation presented by the Council of the Association for services to his colleagues and the people of the state.

Dr. Alfred W. Adson of Rochester presented the citation which read in part:

> . . . we all commend you for your extraordinary service . . . your high ideals, your understanding of human nature, your honest, frugality, loyalty and patience. . . . It is known that you at personal sacrifice have given much of your time during the past twenty-three years in directing the activities of the committee on public policy and entitle you to some relief of that responsibility and to the honorable position of counselor to that committee.

Dr. A. J. Chesley, Secretary and Executive Officer of the Minnesota State Department of Health, was honored for his nearly fifty years of outstanding service in public health work in the United States (and abroad) by being selected as the recipient of the 1948 Distinguished Service Award of the MSMA. Presentation of the medal, a complete surprise to Dr. Chesley, took place at the annual banquet on Tuesday night.

Dr. Leonard S. Arling, of Minneapolis, received the annual medal for the best scientific exhibit by an individual physician presented by the Southern Minnesota Medical Association for his exhibit "What Is Industrial Medicine" Judges who made the selection were: Ernest M. Hammes, Saint Paul; Harold L. Gainey, Kansas City, Kansas; and Sanford S. Sisson, Jacksonville, Florida.

Four members from the list of thirteen eligible to receive certificates citing them for having completed fifty years of practice which entitles them to membership in the Fifty Club were present at the banquet. They were: Dr. Gerhard A. Dahle, Mankato; Dr. Alex E. Hedback and John R. Petersen, Minneapolis; and Dr. William F. C. Heise, Winona. Those unable to attend the banquent were: Drs. Aloysius S. Fleming, Carl J. Lind and N. H. Sheldrup, Minneapolis; Drs. Frank E. Burch, James S. Gilfillan and Asa M. Johnson, Saint Paul; Dr. Leon A. Williams, Slayton; Dr. Joseph G. Parsons, Crookston; and Dr. William B. Torgerson, Oklee.

The Council made the following statement in regard to rebates:

> The Council hereby declares itself as unalterably opposed to all forms of rebates and declares the acceptance

of such as an unethical practice and grounds for disciplinary action by the county societies.

It is recommended that any practice which might give rise to public suspicion that a business arrangement exists between a commercial house and a physician be discontinued.

The Council assures the House of Delegates that it is fully aware of the serious damage to our public relations which has occurred due to the publicity given the government action against the members of our Association.

The Council is alerted and will inform the county societies when it is timely to implement the above suggested action.

Among the numerous matters acted upon by the House of Delegates at the meeting, the following deserve special mention:

Approval of a special assessment of $10.00 on each member starting January 1, 1949, to implement the present public relations program of the State Association.

Reaffirmation of its support of enabling legislation for establishment of county and multiple County Public Health Units and instruction of the Committee on Public Policy to actively support such legislation next year.

After hearing considerable discussion, during which the opposition to the resolution approved by the House last year for having the laboratory of the State Department of Health carry on Rh typing service for physicians of the State was led by members of the Minnesota Society of Clinical Pathologists, the House of Delegates approved a resolution to rescind its former action. Assurance was given by the pathologists that they are adequately staffed and equipped to handle all work of this nature.

The annual report of the Committee on Medical Service recommending an upward revision of the present allowance for medical services to recipients of government aid was approved. These provided for a general over-all increase of 25 per cent after certain items, against which most complaints have been heard have first been raised. The Committee had met with the Minnesota Division of Social Welfare and discussed this whole matter in May, and will now ask that agency to permit these new allowances to become effective July 1, 1948.

The resolution in regard to vaccination with BCG submitted by the Committee on Medical Education and adopted by the House of Delegates seems worth reporting in full:

RESOLUTION

WHEREAS it is a well-known clinical fact that tuberculosis is a disease against which the human body frequently cannot develop strong, dependable, and permanent immunity, and

WHEREAS the use of BCG vaccine is authoritatively reported to provide a relative immunity of varying degree and duration, and

WHEREAS the American Trudeau Society after extensive consideration has said "BCG vaccine, prepared under ideal conditions and administered to tuberculin-negative persons by approved techniques, can be considered harmless

BE IT THEREFORE RESOLVED that the House of Delegates of the Minnesota State Medical Association approve the use of BCG vaccine in the state of Minnesota,

1. Provided that its use be limited to those persons with negative-tuberculin skin-test reactions who may be exposed to unusual hazards of tuberculous infection greater than the danger experienced by the general population, and

2. Provided that vaccination be carried out under conditions which permit prolonged observation of all vaccinated persons, and

3. Provided that the vaccine employed be obtained from the laboratories approved by the United States Public Health Service or the Minnesota State Board of Health, and

4. Provided that all instances of persons vaccinated with BCG vaccine shall be reported to the Minnesota State Board of Health, and

5. Provided that recognition be given to the fact that the use of BCG vaccine is not a substitute for accepted methods of tuberculosis prevention and control, and should not lead to a relaxation of such precautions.

HADDON M. CARRYER, M.D.
Chairman

The Cancer Committee of the Association submitted an outline of a project to be known as "The Cancer Education Service" of the Cancer Committee of the MSMA. (See June issue, page 674).

In considering this project as outlined by Dr. Wells, Chairman of the Cancer Committee, the Council approved the project subject to the declared principles that clinical material shall be used solely for educational purposes and not for the purpose of obtaining free consultation services, and recommended that the use of cancer teams should be arranged through officials of component medical societies only and that the project shall be termed a Cancer Education Service of the Cancer Committee instead of a Cancer Consultant Service as originally proposed.

BLUE SHIELD REPORT FORMS

AT THE present time Minnesota Blue Shield has many Medical Service Report forms in the hands of physicians throughout the state for listing of the services they have rendered Blue Shield subscribers. The majority of these forms will be returned to the Blue Shield office prompt-

ly; others, however, will be tardy and still others will never be returned. Those that are tardy or are never returned are those about which we are concerned. Those which are not returned cause trouble for the office personnel, the Blue Shield subscriber, and also for the attending physician.

First, the Blue Shield office must carry a reserve for unreported and unpaid claims. The delinquent cases increase the accounting procedure and also require extra checking, in that duplicate Medical Service Reports must be sent out each month in the event the original has been lost, misplaced, or overlooked by the physician. This additional procedure requires additional personnel.

Second, the subscriber will write or call the Blue Shield office to inquire as to when his case is to be paid. It is embarrassing to tell him that the report has not been returned from the physician's office, for in some cases the subscriber has received a statement from the attending physician on which no credit is shown for Blue Shield payment. This makes the subscriber wonder whether this organization is slow or whether it is going to make any payment on his claim. At the present time there are cases pending, dating back to January and February, 1948, that are unpaid merely because the attending physician has not returned the completed Medical Service Report form.

Third, the physician is inconvenienced in that he does not receive his payment as promptly as he could. If the physician's statements are sent out without first returning the Blue Shield form, the subscriber frequently gets the impression that the physician is trying to "put something over" on him and collect from him as well as from Blue Shield. We know that this is *not* the case, but some subscribers are difficult to convince.

To sum up, physicians are urged to complete any forms they may have received from the Blue Shield office and return them as rapidly as possible, so that cases may be paid off in the shortest possible time. The first Minnesota Blue Shield claims were paid off on a monthly basis, but with that system some claims were held about two months before payment could be made. In April the procedure was changed to a weekly pay-off basis which made it possible for more cases to be paid before the physician's monthly statements are sent out. This method has proved very satisfactory in that both the physician and the subscriber are better satisfied with Blue Shield service. By paying weekly no completed claim is held in the office over ten days and the Blue Shield staff is justly proud of this, for there are few if any other plans in the country that can boast of such service.

Once again you are urged to return forms promptly and remember, too, that you also benefit in that the sooner the form is returned, the sooner you get paid.

METOPON AVAILABLE

PHYSICIANS who have had patients suffering from severe and persistent pain have realized the shortcomings of morphine and other opium derivatives for prolonged use because of side-effects, such as emesis, constipation, sedation, acquired tolerance, and addiction. The usual need for hypodermic administration is also an inconvenience.

The discovery by Small in 1936 of a substitution product of morphine methyldihydromorphinone, for which the official name of metopon hydrochloride has been adopted, and the determination of its pain-killing properties on oral administration led the Committee on Drug Addiction and Narcotics of the National Research Council to institute an investigation of its clinical possibilities. Physicians were permitted to obtain metopon directly for clinical trial on cancer patients suffering from pain. Conclusions have been drawn from the experience of over 2,000 physicians with over 4,000 patients and were published by the Council on Pharmacy and Chemistry in the May 22, 1948, issue of *The Journal of the AMA* (page 365).

The report indicates that metopon is a valuable pain killer, even on oral administration, and has little tendency to produce the undesirable side actions commonly experienced with morphine. While not by any means entirely effective in preventing withdrawal symptoms in morphine addicts, it is of some value as a substitute. Its most satisfactory results are obtained if used in the relief of pain before too much reliance has been put upon morphine.

Metopon can now be obtained on prescription at the pharmacies in 3 mg. capsules only. It is a narcotic and subject to the same regulations as other narcotics. Attention is drawn to the min-

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

MEDICAL GROUP SEEKS TO UNITE WORLD PHYSICIANS

Doctors of forty-six nations are now represented in an international organization designed to promote health throughout the world—the World Medical Association. Thus another step toward the realization of international understanding and peace through the provision of a means of jointly meeting some of the mutual problems faced the world over has been taken. This association, together with the newly formed World Health Organization, which is now virtually assured full U. S. support, is a bright spot in an otherwise sober international picture.

Created in Paris, September 18, 1947, the World Medical Association had been exactly one year in the making, with thirty-two national medical associations working together to draw up the plans. Prominently figuring in the promotional work is the American Medical Association. Dr. Louis H. Bauer, Hempstead, New York, is one of the ten administrative councilors elected by the delegates to the organization meeting; headquarters of the association will be in New York.

Closest possible liaison with the United Nations Educational, Scientific and Cultural Organization (UNESCO) and with the World Health Organization is to be maintained so as to keep the medical profession throughout the world in touch with these and other groups whose activities lie in medical and health fields.

Seven Basic Objectives

The primary objectives of the World Medical Association have been outlined as follows:

1. To promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available.

2. To maintain the honor and protect the interests of the medical profession.

3. To study and report on the professional problems which confront the medical profession in the different countries.

4. To organize an exchange of information on matters of interest to the medical profession.

5. To establish relations with, and to present the views of the medical profession to, the World Health Organization, UNESCO and other appropriate bodies.

6. To assist all peoples of the world to attain the highest possible level of health.

7. To promote world peace.

There is considerable evidence that these objectives will receive strong world support.

It is significant that Prague, Czechoslovakia, was selected for the 1948 meeting in view of its long medical history. Desirability of a European meeting place stems from the travel problem for delegates from Europe and their inability to afford a long trip. Prague physicians are hoping that an assembly of medical men from all over the world might stimulate a restoration of this former great teaching center.

To Maintain Local Committees

In addition to the general office and secretary in New York, it is planned that the World Medical Association shall have assistant secretaries in strategic areas of the world as well as local committees in each nation.

It is also planned to publish a journal of the activities of the association in three languages—English, French and Spanish. Financing of the association presents certain grave difficulties, it is noted. Some countries restrict their citizens' spending money too extensively outside of their own particular borders, while in other countries there is utter economic chaos. It is not expected that the association will be self-supporting very soon; it will undoubtedly have to rely on financial assistance from outside. Many organizations and individuals have pledged to contribute substantial

sums, which will enable the association to go ahead with present plans.

The Council of the World Medical Association is exploring the possibility of making arrangements whereby funds advanced to the association will not be taxed by the respective countries.

Participating Nations Listed

In addition to the United States, forty-five nations are participating in the World Medical Association: Argentina, Australia, Austria, Belgium, Brazil, Bulgaria, Canada, Chile, China, Colombia, Costa Rica, Cuba, Czechoslovakia, Denmark, Egypt, Ecuador, France, Great Britain, Greece, Guatemala, Honduras, Hungary, India, Iraq, Ireland, Italy, Luxembourg, Mexico, Netherlands, Nicaragua, Norway, Palestine (both Arab and Jewish states), Panama, Peru, Poland, Portugal, Puerto Rico, San Salvador, Spain, Sweden, Switzerland, Turkey, Uruguay, and Venezuela.

Out of courtesy to the nation entertaining the organizational meeting of the World Medical Association, Professor E. Marquis, Director of the School of Medicine of Rennes, France, was elected first president. Dr. Thomas C. Routley, Canada, was chairman of the organizing committee. Dr. Charles Hill, secretary of the British Medical Association, was elected honorary secretary until such time as a permanent secretary is appointed; Dr. Otto Leuch, Switzerland, is honorary (temporary) treasurer.

One of the first resolutions to be passed by the new group is one which gives strong evidence of the humanitarian motives behind the new association. It is to be presented for acceptance by physicians throughout the world:

> My first duty, above all other duties written or unwritten, shall be to care to the best of my ability for any person who is entrusted to or entrusts himself to me, to respect his moral liberty, to resist any ill treatment that may be inflicted on him, and, in this connection, to refuse my consent to any authority that requires me to ill-treat him.
>
> Whether my patient be my friend or my enemy, even in time of war or in internal disturbances, and whatever may be his opinions, his race, his party, his social class, his country, or his religion, my treatment and my respect for his human dignity shall be unaffected by such factors.

PUBLIC HEALTH DISCUSSED AT 95TH ANNUAL MEETING

A prominent feature of the ninety-fifth annual meeting of the Minnesota State Medical Association, held in Minneapolis last month, was an afternoon session devoted to a discussion of public health problems.

Health was viewed as a continuing job, which, as our standards continue to advance, will always remain unfinished. A panel of distinguished speakers, each of whom was qualified by wide experience in his particular field, presented the viewpoint that health is not merely the physical condition of an individual; it embraces, rather, a number of important factors — employment, wages, education, housing, standards of living, physical facilities—and a host of other considerations.

Speakers included Dr. John O. Christianson, superintendent of the University of Minnesota School of Agriculture; Dr. Lloyd E. Harris of the Section on Pediatrics of the Mayo Clinic and the Rochester Child Health Institute; Dr. Robert L. Novy, Detroit, president of Michigan Medical Service; and Dr. Morris Fishbein, Chicago, editor of the *Journal of the American Medical Association*. Senator Ball was to have appeared, but because of the press of legislative duties, he had to cancel out. His prepared talk was read by Dr. Reuben F. Erickson, Minneapolis, chairman of our State Committee on Public Policy.

Meeting Well Attended

Approximately 500 persons attended the public health meeting, to which allied professionals as well as the public at large were invited.

Dr. Christianson told of the part which the leaders of farm and rural groups must play in promoting health and urged that the medical profession continue its efforts to extend health education. Dr. Novy outlined the need for the spread of voluntary health insurance as a method of budgeting for medical and hospital expenses.

Bringing a healthy child into the world and keeping him healthy in mind and body was described by Dr. Harris as the real "first line of defense" in this country. He pointed out that every child should have the best possible start in life, which includes adequate prenatal and childbirth care for every mother; proper attention throughout infancy—scientific nutrition, immunization

against preventable disease and proper mental environment—as well as watchful guidance throughout childhood. These aims, he pointed out, are among several included in the over-all health program of the American Medical Association, which the medical profession stands ready to carry out with the help of an intelligent public.

Federal Program Unlikely

Senator Ball's message revealed that compulsory health insurance does not stand a chance of being enacted by the Eightieth Congress. He said that "the whole trend in Congress in the past three years has been away from further experiments in socialization rather than toward them."

Mr. Ball outlined some of his own views as to the development of a "sound federal health program" including "a positive rather than a negative approach to health . . . co-ordination of veterans medical care and the public health service . . . expansion in research . . . federal aid for more adequate sewage disposal where needed . . . health education . . . and further assistance to states for medical care for indigents."

Senator Ball concluded that "the United States will achieve far greater and more rapid progress in the field of public health, as in others, if it sticks to the principles of freedom through which so much has already been achieved."

Teamwork in Health Cited

The "magnificent teamwork" of people in the health professions has enabled the United States to reach its present outstanding standard of health, Dr. Fishbein told the conference.

He paid tribute to the countless workers who have contributed to U. S. health—physicians, public health workers, social workers, hospital administrators, technicians, clinical pathologists, sanitary engineers, entomologists, nurses, dieticians, and medical record librarians. He cited particularly the work done in the field of tuberculosis as one of the conspicuous examples of what he termed "teamwork in the conservation of human resources."

The outstanding feature of American medicine today, Dr. Fishbein declared, is its continuation in the field of what is commonly called private enterprise. He then pointed to the importance of the general practitioner to the maintenance of our present system of medical care.

"The general practitioner is the functioning unit of American medicine," Dr. Fishbein said. "Upon him devolves the duty of being the first to detect disease and the first to give proper care for the vast majority of conditions for which people consult doctors."

Dr. Fishbein concluded that "in every phase of medical care in our nation today there is teamwork. It is a teamwork that has grown out of the needs of man, but principally out of the advancement of medical science and a recognition of the necessity for co-operation, co-ordination and integration for maximum achievement."

REGIONAL HEALTH DAY MEETINGS PLANNED

The State Medical Association, the Woman's Auxiliary and the Minnesota Department of Health have joined forces in planning a series of regional health day meetings this fall to include every section of Minnesota. Eight such meetings are to be scheduled in the following locations: Bemidji, Crookston, Duluth, Fergus Falls, Mankato, Rochester, St. Cloud and Willmar.

Sponsored by the local medical societies and their auxiliaries and the public health department personnel in each community, local citizen participation and interest will be actively sought in the round-table and general meeting discussions on timely health topics for which the profession will serve as consultants.

METOPON AVAILABLE

(Continued from Page 808)

imal initial dose of 6 mg. for patients who have not been taking other opium derivatives, if satisfactory analgesic effect is to be expected. Those who have had previous opiates will probably need 9 mg. or more initially. Effects are said to last from five to ten hours, and repeat doses and intervals depend on various factors, those who have had previous narcotic medication requiring larger and more frequent doses. In substituting metopon for other opiates, rapid reduction rather than abrupt discontinuance of the previous medication is advisable.

In Memoriam

JOHN C. M. BRUST

Dr. John C. M. Brust, who was a fellow of the Mayo Foundation in 1932 and received an M.S. in proctology from the University of Minnesota in 1934, died May 14, 1948, in Syracuse, New York.

WILLIAM CHARLES EHMKE

Dr. William C. Ehmke of Willow River, Minnesota, passed away at his home on May 9, 1948, following a heart attack.

Dr. Ehmke was born January 20, 1881, in Le Sueur County, Minnesota. He attended Le Sueur High School and obtained his M.D. degree at the Minneapolis College of Physicians and Surgeons in 1905. In 1906, he went to Willow River as the company doctor for the Atwood Lumber Company. He practiced there until his death. He was a member of the East Central Medical Society, the Minnesota State and American Medical Associations.

On the occasion of his sixty-fifth birthday, January 20, 1946, the people of Willow River celebrated in his honor the completion of forty years of distinguished service to the community. During that time he had been very active in civic affairs. He was mayor for over twenty years and a member of the school board for over thirty years, acting most of the time as president of the board.

On November 28, 1907, Dr. Ehmke married Pearl Soliday. He is survived by his wife and three sons, William and Lyle of Willow River and Donald of Willmar; one brother and three sisters.

GEORGE B. HAMLIN

Dr. George B. Hamlin of Minneapolis died at his home May 3, 1948. He was seventy-seven years of age.

Dr. Hamlin was born in Minnesota on February 10, 1871. He was a University of Minnesota Medical School graduate, having received his degree in 1896.

He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations. He had received the certificate of recognition for fifty years of medical practice from the Minnesota State Medical Association.

Dr. Hamlin is survived by his wife, two sons, Lehan and Maurice of Minneapolis, and a brother, Ernest T. Hamlin of Santa Barbara, California.

SERGEANT P. MARTIN

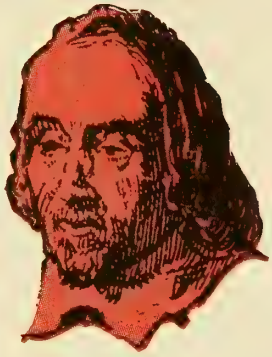
Dr. Sergeant P. Martin, a fellow in surgery at the Mayo Foundation from 1913 to 1917, died January 8, 1948, in Kenmore, New York, at the age of sixty-one. Dr. Martin practiced urology in Buffalo, New York, after leaving the Mayo Clinic.

JOHN C. SERKLAND

Dr. John C. Serkland, a practitioner at Rothsay, Minnesota, since 1900, died on May 9, 1948, at the age of seventy-six.

Dr. Serkland was born February 23, 1872, at St. James, Minnesota. After receiving his M.D. degree at the University of Minnesota in 1900, and after a short period of practice in Minneapolis, he located at Rothsay.

In June, 1904, Dr. Serkland and Berthe Seline Pedersen of Rothsay were united in marriage. Mrs. Serkland passed away in 1912. They were blessed with three children, Alice, Alvin and Chester, who are all living. In 1920, Dr. Serkland married Anna Langeland, who survives him.



Dr. Serkland was a member of the Park Region District and County Medical Society, the Minnesota State and American Medical Associations. Besides giving devoted medical care to his locality, he was much interested in civic affairs, serving two terms as mayor of the village, was a member of the council and school board, and was a trustee of the Hamer Lutheran church. He held membership in the Sons of Norway, the Lutheran Brotherhood and the IOOF. According to the *Rothsay Argus,* "Dr. Serkland's complete honesty and sincerity carried him the friendship and respect of his community and of a wide circle of acquaintances in this area. The memory of their family doctor will long remain with the people on the farms and in the village of Rothsay."

GEORGE ELMER STROUT

Dr. G. Elmer Strout of Minneapolis died at his home, May 10, 1948, at the age of seventy-four.

Dr. Strout was born in Fargo, North Dakota, December 23, 1873. He graduated from the University of Minnesota Medical School in 1901, where he was a member of Phi Delta Theta and Nu Sigma Nu fraternities. He had practiced ophthalmology and otolaryngology in Minneapolis since 1917 and had been an associate professor at the University of Minnesota Medical School for some ten years. He was also associated with the Nicollet Clinic. A member of the Hennepin County Medical Society, he was also a member of the Minnesota State and American Medical Associations. Dr. Strout was also a director of the Wells Memorial house, a Mason, and a member of the Zuhrah Temple of the Shrine and the Minneapolis Club of St. Mark's Cathedral.

Dr. Strout is survived by his widow and a daughter, Mrs. Jack B. Hall of Minneapolis, and four brothers.

Wm. Harvey

(1578-1657)

Discovered and demonstrated the circulation of the blood and the heart's function.

A most important milestone in cardiotherapy was the introduction of Aminophyllin. Its action in stimulating the myocardium to increased vigor of contraction results in augmented cardiac output and increased work.

SEARLE AMINOPHYLLIN*

—has exhibited its efficacy also in relieving bronchial asthma, paroxysmal dyspnea and restoring Cheyne-Stokes respiration to a more normal rhythm.

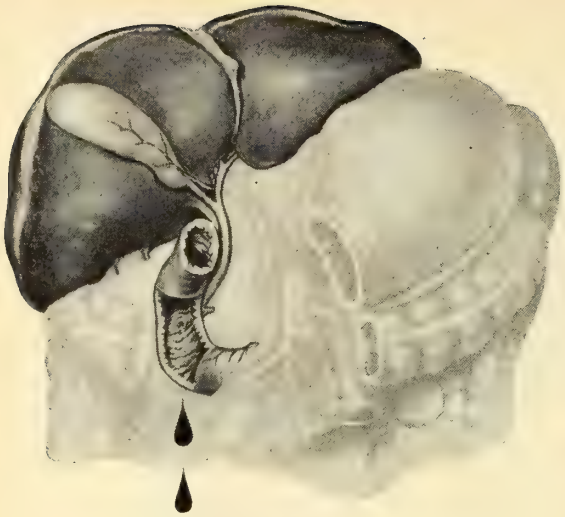
Not all little acorns into great oaks grow.



Nor do all little children reach optimal height.

Nutritional elements absolutely essential to optimal growth and function are today available in convenient economical forms. Vitamins D and A—alone or combined with other growth and health promoting vitamins—are provided in potencies suited to supplementation, maintenance, and prophylaxis through infancy, childhood, adolescence, and adulthood, for as long as growth and life persist.

Upjohn Vitamins

OBJECT:
DRAINAGE

In discussing the management of chronic cholecystitis without stones, Albrecht states:

"The object of the medical procedure is to assist in draining an infected organ."*

The specific hydrocholeretic action of Decholin (chemically pure dehydrocholic acid) accomplishes this purpose.

Decholin induces bile secretion which is thin and copious, flushing the passages from the liver to the sphincter of Oddi, and carrying away infectious and other accumulated material.

How Supplied: Decholin in 3¾ gr. tablets. Packages of 25, 100, 500 and 1000.

*Albrecht, F. K.: Modern Management in Clinical Medicine, Baltimore, The Williams and Wilkins Co., 1946, p. 170.

which he had developed. Approximately 600 delegates to the convention from all parts of the United States, Canada and Hawaii attended the meeting.

* * *

Due to incorrect information, it was announced in the June issue that Dr. H. Robert Ransom was leaving Osseo to establish practice in Crosby. Word has come from Dr. Ransom that he is remaining in Osseo, where he is associated in practice with Dr. T. J. Bloedel.

* * *

The Jaracki Memorial Lecture was delivered by Dr. Virgil S. Counseller, Rochester, at Jewish Hospital in Philadelphia on May 22. The title of Dr. Counseller's lecture was "A Clinical and Surgical Review of Vesicovaginal Fistula."

* * *

Construction work began early in June on a 35-foot addition to Dr. Robert A. Glabe's office building in Plainview. To be part of the new addition are rooms for diagnostic equipment and records, a darkroom, a minor surgery room and a recovery room.

* * *

During June, Dr. Walter S. Neff of Virginia attended a postgraduate course in "Physiological Basis for Internal Medicine," which was presented by the American College of Physicians at the University of Illinois College of Medicine.

* * *

An M.S. degree in physiology was awarded to Dr. John W. Braasch, Rochester, on June 18 at the commencement exercises of the University of Illinois Chicago Professional College. Dr. Braasch is the son of Dr. and Mrs. W. F. Braasch of Rochester.

* * *

After a year in association with Dr. A. D. Hoidale and Dr. W. G. Workman in Tracy, Dr. O. J. Esser closed his practice early in June and returned to his previous residence in New Ulm. He planned an extended vacation before resuming his professional work.

* * *

"Child Care" was the title of a talk given by Dr. F. H. Walter of International Falls at a meeting of the Women of Moose Chapter in International Falls on May 26. Dr. Walter is affiliated with the International Falls Clinic.

* * *

Dr. Anthony Rosyzki, formerly of Blackduck, was recently discharged from the army after being stationed for a year at Honolulu. Dr. Rosyzki, visiting in Bemidji in June, planned to locate some place in Minnesota to begin his practice.

* * *

During June, Dr. Chester Thiem maintained the practice purchased in Gibbon by Dr. John Glaeser, thus providing Gibbon with a physician until Dr. Glaeser was discharged from the army. After July 1, Dr. Thiem began work at Ancker Hospital in Saint Paul.

* * *

Early in June, Dr. Albert E. Krieser announced the opening of offices for the practice of medicine and surgery in Mankato. His practice will be directed primarily to the diagnosis and treatment of diseases of the chest.

(Continued on Page 818)

LET US TASTE IT FOR YOU, DOCTOR!

. . . We are well aware of the fact that these are busy days for you, Doctor. That is why Minnesota Medicine has taken the responsibility of acting as "official taster" of advertising and avoiding the presentation of products which are of questionable value . . .

. . . No product subject to the review of A.M.A. councils can be advertised in Minnesota Medicine until acceptance is secured. This insistence upon high standards has resulted in a loss of many pages of advertising, but it has given us the satisfaction of knowing that no subscriber of Minnesota Medicine will in any way suffer from use of products introduced to him through his official state professional magazine . . .

. . . Our advertisers are always interested in proof that their message is seen. Most offer free samples and literature. Just a penny postal from you will serve to indicate that Minnesota Medicine is read . . . Make it a habit, for in that way both of us profit: You learn more about new products of proven value, and we can show our advertisers that physicians of the state read their professional house organ.

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address: Registrar, 427 S. Honore St., Chicago 12, Ill.

(Continued from Page 816)

A graduate of the University of Loyola School of Medicine, Dr. Krieser practiced for a short time in Mankato before enlisting with the Mankato National Guard unit in 1941. After five years in the army medical corps, he was discharged and became a staff physician at the Ah Gwah Ching Sanatorium.

* * *

The role of psychosomatic medicine in literature was discussed by Dr. Frances J. Braceland, consulting psychiatrist at the Mayo Clinic, at a meeting of the Minnesota Assocation of Hospital and Medical Librarians on June 3 in Minneapolis.

* * *

Among speakers at the Sixth District meeting (part of the Wisconsin State Medical Society) in Green Bay, Wisconsin, on June 12 was Dr. H. E. Michelson, professor of dermatology at the University of Minnesota, who discussed "Dermatology for General Practitioners."

* * *

Two papers were presented by Dr. J. Arnold Bargen, Rochester, at a meeting of the New Mexico State Medical Society in Las Vegas, New Mexico, on June 3 and 4. Titles of the papers were "Management of Lesions of the Small Intestine" and "Management of Intestinal Obstruction."

* * *

It was announced on June 9 that Dr. Donald C. Balfour, director emeritus of the Mayo Foundation, had been elected a member of the Carleton College board of trustees at a meeting of the board on June 7. In 1934 Carleton College conferred upon Dr. Balfour the honorary degree of Doctor of Laws.

* * *

An "Outstanding Achievement" medal was presented by the University of Minnesota to Dr. William W. Will of Bertha at an alumni dinner on June 11 in Coffman Memorial Union. Dr. Will was recently named by the Minnesota State Medical Association for the AMA award for outstanding general practitioner.

* * *

A new physician in Excelsior is Dr. Elaine McKenzie, who recently became associated in practice with Dr. Lewis M. Reid of that city. A graduate of the University of Minnesota Medical School, Dr. McKenzie served her internship at Minneapolis General Hospital. She is married to Roy R. McKenzie, a chemical engineer.

* * *

Guest speaker at the annual dinner meeting of the Otter Tail County Public Health Nursing Service, held June 3 at Fergus Falls, was Dr. Hilbert Mark, director of the division of tuberculosis of the Minnesota Department of Health. Dr. Mark outlined the procedure for organizing the county for a mass chest x-ray survey.

* * *

Eleven Minnesota physicians were among the speakers at the forty-fourth annual meeting of the National Tuberculosis Association in New York during the middle of June.

In the group were Dr. H. Corwin Hinshaw, Rochester; Dr. William Roemmich, Hennepin County tuberculosis

(Continued on Page 820)

Speakers and Entertainers Who Wear Glasses Will Appreciate MAY-O-LITE

Entertainers and speakers find it important to establish a relationship with their audience through eye-contact.

A speaker or entertainer seldom realizes that reflected light upon the surface of his glasses can be a cause of an unresponsive audience. MAY-O-LITE answers this problem.

MAY-O-LITE is a scientific method of cutting down annoying surface reflections upon lenses. With MAY-O-LITE these reflections are reduced from 80 to 95 per cent, eye strain is minimized and lenses become far more resistant to scratches.

Whether or not your patients are public speakers or entertainers, tell them about MAY-O-LITE.

MAY-O-LITE Low Reflection Lens Coating has been developed by the May Research Company. Write for a descriptive pamphlet and a treated sample of glass, today.

control officer; Dr. F. J. Hill, Minneapolis health commissioner; Dr. Thomas J. Kinsella, Minneapolis; Dr. E. S. Mariette, medical director of Glen Lake Sanatorium, and Dr. Sumner S. Cohen, Dr. L. M. Larson, Dr. P. M. Mattill, Dr. F. C. Nemec, Dr. E. P. K. Fenger and Dr. V. K. Funk, staff members of Glen Lake Sanatorium.

* * *

Dr. Elmer C. Paulson, formerly of Elbow Lake, moved to Minneapolis late in June after receiving an appointment to a fellowship in radiology at the University of Minnesota Medical School. Dr. Paulson, a Fergus Falls resident before the war, had opened a practice in Elbow Lake following his discharge from the army in 1946.

* * *

It was announced in Bemidji on May 20 that Dr. G. A. Miners, formerly of Deer River, had arrived in Bemidji to assume the duties of director of District 1, Minnesota Department of Health. Dr. Miners fills the position previously held by Dr. P. T. Watson, who was transferred to the state office in Minneapolis in January, 1947.

* * *

Five Edina (Minneapolis suburb) physicians offered their services early in June in conducting free examinations of all youngsters participating in the Edina Park Board's supervised swimming classes at Lake Calhoun. The physicians who volunteered to perform physical examinations were Dr. Francis M. Walsh, Dr. Mary Galligan, Dr. Robert Tinkham, Dr. C. V. Rockwell and Dr. I. H. Moore.

* * *

The seventy-fifth birthday anniversary of Dr. C. S. Bossert, Mora, was celebrated by a surprise dinner party for him at the Braham Hospital on May 27. Dr. Bossert has been a staff member of the hospital since it opened in December, 1947. A graduate of the University of Pennsylvania in 1908, Dr. Bossert has been located in Mora since 1914.

* * *

The sixteenth annual convention of the American Society of Medical Technologists was held in Saint Paul during the week of June 7. About 500 delegates from throughout the country attended. Convention activities included a seminar in hematology at the University of Minnesota Continuation Center and a trip through the Mayo Clinic in Rochester.

* * *

Principal speaker at the first annual countywide Public Health Dinner, held in St. James on May 19, was Dr. R. N. Barr of the Minnesota Department of Health. Speaking on the topic, "Economic Conditions of Public Health," Dr. Barr explained how money for public health is used and how public health districts are set up. He also described some of the recent health legislation.

* * *

After thirty-six years of school service in Tracy—twenty-four of the years as president of the school board—Dr. W. H. Valentine was honored at a ceremony on May 28 by members of the local high school senior

class and by the Tracy Civic and Commerce Association. In observation of his retirement from the school board, scheduled for July 1, Dr. Valentine was presented with an honorary plaque and a desk pen set.

* * *

The Hopkins post of the Veterans of Foreign Wars planned to honor Dr. James Blake, pioneer Hopkins physician, in a special ceremony during the 1948 Raspberry Festival, an annual celebration in the city. Three of Dr. Blake's sons, physicians all, Drs. James A., Allan and Paul, are members of the Hopkins VFW post. Details of the ceremony had not yet been worked out at the time announcement was made of the proposed honor.

The degree of doctor of science (opthalmology) was conferred upon Dr. Bourne Jerome, Minneapolis, by the University of Pennsylvania on June 9. The degree was granted for graduate work carried on at the school by Dr. Jerome both before and after service in the recent war. A graduate of the University of Minnesota Medical School in 1935, Dr. Jerome is associated in the practice of opthalmology with Dr. Karl E. Sandt and Dr. W. J. Bushard, Minneapolis.

* * *

The President's Certificate of Merit was presented to three Mayo Clinic staff members in a ceremony at Rochester on May 18. Receiving the award were Dr. Earl H. Wood, Dr. Edward H. Lambert and David M. Clark. Mr. Clark is a textile engineer who worked with the two doctors in developing a pilot's anti-blackout g-suit. Presentation of the Certificate of Merit was made by Rear Admiral F. L. Conklin, commandant of the ninth naval district.

* * *

Principal speaker at the third annual medical conference sponsored by the Minnesota American Legion at Fort Snelling on June 10 was Major General Carl R. Gray, Jr., national head of the Veterans Administration. The conference, to discuss the present and future status of medicine and hospitalization for veterans, was attended by veterans' officials from Minnesota, North Dakota, Nebraska and Iowa, and by physicians from the University of Minnesota Medical School and the Mayo Clinic.

* * *

On May 20, Dr. J. F. DuBois of Sauk Centre was reappointed by Governor Luther Youngdahl as a member of the State Board of Medical Examiners. First appointed to the board in 1927, Dr. DuBois will serve for a seven-year term.

Earlier in the week, at a meeting of the Sauk Centre Rotary Club, Dr. DuBois said that over-specialization in medicine is leading towards socialism. "Our system grew up around the family doctor," he stated. "If everyone specializes, there will be only one agency which can afford medical care. That is the government—in other words, socialized medicine." He said that socialized medicine would be "the entering wedge for socialism

throughout the country." He urged that the best way to meet problems of medicine was by internal action of the profession itself against over-specialization and by preparatory plans on the part of the general public to insure themselves in recognized hospitalization and health plans.

* * *

Honored at the recent meeting of the Minnesota State Medical Association for completing fifty years of medical service in the state were thirteen Minnesota physicians.

The thirteen practitioners, each with at least fifty years of state practice to his credit, were Dr. Gerhard A. Dahl, Mankato; Dr. William F. C. Heise, Winona; Dr. Aloysius S. Fleming, Dr. Axel E. Hedback, Dr. John R. Peterson, Dr. Carl J. Lind and Dr. N. H. Sheldrup, all of Minneapolis; Dr. Leon A. Williams, Slayton; Dr. Frank E. Burch, Dr. James S. Gilfillan and Dr. Asa M. Johnson, all of Saint Paul; Dr. Joseph G. Parsons, Crookston, and Dr. William J. Torgerson, Oklee.

* * *

Golfers who complain at driving five or ten miles to play golf should consider the determination of Dr. J. J. Catlin of Buffalo. He drives ninety miles for a game of golf, and does it two or three times a week!

Always on Thursday and usually on Sundays and Wednesdays, the sixty-seven-year-old physician makes the forty-five mile jaunt from Buffalo to the Twin Cities to try out the various Saint Paul and Minneapolis courses. In addition, he plays almost every evening on the Buffalo golf course. Dr. Catlin, who didn't start playing golf until he was over forty, says that golf is the "best medicine in the world. I tell all my patients to try it." He usually shoots in the 80's.

BLUE SHIELD NEWS

Persons covered by Blue Shield as of June 15, 1948—26,369
Number of Blue Shield cases paid on June 15, 1948—201
Total for 1948—553

Amount paid on Blue Shield cases on June 15, 1948—$ 7,083.50
Total for 1948— 20,486.16

At the convention of the Minnesota State Medical Society June 7, 8, and 9, 1948, in the Minneapolis auditorium, the Minnesota Blue Shield exhibit consisting of material pertaining to the Blue Shield plan was set up mainly to answer questions raised by the doctors attending the convention and also to enroll any doctors who were not Blue Shield participating doctors of medicine. Of the few additional doctors who were signed up, it was found that they had either just completed their internship or recently returned from service. We are very glad to add their names to the roll of Blue Shield participating doctors of medicine.

There were many requests for information pertaining to Blue Shield. The largest request was for Blue Shield representatives to visit the towns and also for them to call at the doctor's office for discussion. As a result all representatives have been instructed to call on the doctors in the towns they visit, so calls from them can be expected.

A frequent query was, "When is Blue Shield going to be offered in our town?" It will be offered in all towns just as soon as possible. At the present time there are twenty representatives in the state. We know this number is inadequate, but more are being put on all the time. At present these representatives are only following up groups that have requested enrollment, because we feel that it is only fair that the established groups should have Blue Shield first. In the Blue Shield office there are hundreds of cards requesting representatives to discuss enrollment with groups, and these requests are getting first priority. Therefore, if a representative does not get to your town immediately, please be patient, for one will be there soon.

It was suggested by some of the doctors attending the convention that material be supplied for their waiting rooms. Blue Shield literature for this purpose is being prepared and will be sent to you.

When the Blue Shield representative calls on you please give him any requests you may have received for group enrollment, also ask him any questions you may have or give him any suggestions. He will return them to this office and necessary action will be taken.

May we again state that this is your plan and it is within your power to make or break it. Those of us in the office do not know how you feel about Blue Shield unless you voice your opinions. We are always open to suggestions and want them. So help us make your plan the best.

Reports and Announcements

IDAHO STATE MEDICAL ASSOCIATION

The entire guest faculty for the fifty-sixth annual session of the Idaho State Medical Association, held July 6 through 8 at Sun Valley, Idaho, consisted of five University of Minnesota Medical School staff members. The five lecturers were Dr. Owen H. Wangensteen, director of the department of surgery; Dr. Donald W. Hastings, chief of psychiatry and neurology; Dr. Edward P. Burch, assistant professor of ophthalmology; Dr. Frederick W. Hoffbauer, assistant professor of medicine, and Dr. Leonard A. Lang, clinical assistant professor of obstetrics and gynecology.

MINNESOTA SOCIETY OF INTERNAL MEDICINE

The semi-annual meeting of the Minnesota Society of Internal Medicine was held as a one-day session in Duluth on June 5. Fourteen papers and discussions comprised the program, which was presented at St. Mary's Hospital.

In charge of the session was Dr. D. W. Wheeler, Duluth, president of the society. Among papers presented by Duluth physicians were "Acute Coccidioidomycosis" by Dr. Sam H. Boyer, Jr.; "Acute Coronary Inadequacy" by Dr. Robert L. Nelson; "Hyperparathyroidism" by Dr. J. J. Coll, and "A Ten-Year Review of Seventy-five Cases of Uremia" by Dr. Arthur H. Wells and Dr. William D. Coventry. Other scientific discussions were given by physicians from Rochester and the Twin Cities.

FEE SCHEDULES FOR PUBLIC AGENCIES

(Continued from Page 758)

to render better medical care to groups cared for from public funds, and while we want free choice of physician and fee for service, we must accomplish this in both an efficient and an ethical manner. Eventually what is best for the public will be best for the medical profession. Our plans must include the full use of existing institutions such as state hospitals for insane and tuberculous as well as charitable institutions. In particular, plans must be made to provide our teaching institutions with ample teaching material.

The medical profession will need to accept the entrance of the agencies into this effort. To them must go the responsibility for determining who is entitled to care. Also to them must go the right to infringe on free choice of physician. In Nebraska very definite limitations are placed on what osteopaths, chiropractors and optometrists can do. Likewise, some limitation must be placed on what doctors of medicine can do. All doctors are certainly not capable of rendering all types of medical care. In special cases, specialists' care must be obtained. The officers of the agencies will need to have directive authority in these cases. Here, in particular, the medical profession must give wise and conscientious counsel, and this counsel must be accepted by the agencies.

The Nebraska State Medical Association is suggesting that agencies paying for medical service from public funds, and members of the medical profession, study our schedule carefully; that they use it in making agreements for medical service; that in cases where the printed fees seem too high or too low, they bargain only on where to place the unit value; that information as to agreements be promptly forwarded to the state medical office. We also request of the profession that suggestions as to changes in the number of credits be sent to the state medical office.

This effort can come to naught, or it can be an instrument of advantage to all and an important step toward better relationship between the medical profession and the public.

Glenwood Hills Hospitals Pioneered

FOR SOME YEARS we have been offering just such a course as is advocated . . . . . →

Thanks to you, registered physicians, the June class for this one-year course was oversubscribed.

Modern methods, modern nursing, modern patient care as exemplified here have made our graduates the most desired by doctors and organizations. . . . They graduate well trained, loyal, eager to serve.

O

The most capable of these graduates are the ones who come doctor-recommended.

MINNESOTA REPRESENTATIVE—S. E. STRUBLE, WYOMING, MINN.

WHEN interviewed between platefuls, this 11-months-old young man emphatically stated: "I have been brought up on Pablum and still like it, but some days when I'm in the mood for oatmeal, nothing satisfies me like Pabena!"

Nutritious, quick and easy to prepare, both products are for sale at drug stores.

MEAD JOHNSON & COMPANY, EVANSVILLE, IND., U.S.A.

documented!

over 200 published reports

Leading clinics, distinguished journals, and outstanding investigators bear witness to the excellent clinical results with BENADRYL for allergy in its manifold varieties. What other antihistaminic can offer so extensive a bibliography of clinical research?

a remarkable record

BENADRYL is not only valuable as an all-round antihistaminic but has a truly remarkable record in the relief of hay fever. A recent study of 425 cases, for example, shows 82.4% satisfactory improvement. Similarly, in vasomotor rhinitis 76.7% of 349 cases were benefited. Lacrimation, sneezing, and nasal stuffiness are frequently controlled within an hour after a single dose of BENADRYL and the effect often endures from 5 to 8 hours.

symptomatic relief with minimal side effects

in hay fever

PYRIBENZAMINE

During the last two pollen seasons, the effectiveness of Pyribenzamine hydrochloride in hay fever has been demonstrated repeatedly . . . 84% of 288 cases[1] – 78% of 588 cases[2] – 82% of 254 cases.[3]

Side effects are few and for the most part mild: – "No serious side effects have been noticed in any patients."[1] "In our opinion, reactions to Pyribenzamine are minimal and seldom necessitate stoppage of the drug."[4] The usual adult dose is 50 mg. four times daily.

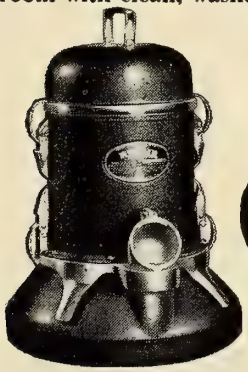
POUR DIRT AWAY

with

Rexair

Wouldn't you like to get rid of dusty vacuum bags forever? Wouldn't you like to pour dust away as easily as dirty dishwater?

You can, with Rexair—the amazing new home appliance that collects dust in water instead of a bag. You just pour the water down the drain and flush—dust and dirt go with it.



When you clean with Rexair, you clean *clean*. Rexair has no porous bag through which dust can escape back into the air you breathe. Instead, the air passes through a churning bath of water which wets down the dust and returns only dust-free air to the room. Wet dust cannot fly, and dust cannot escape from Rexair's water basin.

Rexair does dozens of household jobs. Rexair cleans rugs, drapes, and upholstery; scrubs, rinses, and dries floors; dusts furniture; waxes and moth-proofs. Rexair improves even the air you breathe—takes in dust and dirt-laden air and fills the room with clean, washed air.

FREE BOOK

Learn more about Rexair! Send for this free, illustrated 12-page book. Shows how Rexair does dozens of household jobs, how it even cleans the air you breathe. Ask for as many copies as you need.

The First Narcotic . . .

Medicine and Dentistry thank a young Prussian drug clerk, Friedrich Sertürner (1784-1841), for isolation of the first pure alkaloid of opium, morphine—named for Morpheus, god of Dreams, son of Somnus, god of Sleep.

A physician's lament over the unreliability of opium prescriptions spurred Sertürner to a 15-year search for the secret locked in the juices of the poppy plant. His addition of ammonia to an opium solution in 1806 caused a formation of gray crystals, from which he succeeded, in 1816, in wresting the real *principium somniferum*—morphine itself.

In its wake have come not only all the barbiturates and milder anodynes, but also many alkaloids isolated by methods similar to Sertürner's: heroin, emetine, quinine, vertabrine, strychnine, etc.—pure, dependable drugs bringing new standards to medicine and dentistry.

★ ★ ★

And Doctors After 1899 found new standards in malpractice protection—the *complete*, *preventive* and *confidential* counsel and service provided for physicians and dentists by the Medical Protective policy.

ST. PAUL, MINNESOTA

HEADQUARTERS

Wherever the Authorized Camp Service sign appears, you can depend upon the dealer as the "Headquarters" for Camp Anatomical Supports in that community. Whether it be a special Camp Department in one of the large metropolitan department stores, or whether it be a small neighborhood store, specialty shop or surgical supply dealer anywhere in the world — you can send your patients there with complete confidence in two things: (1) Your prescriptions will be carefully executed by expert fitters trained by the Camp organization to fill such prescriptions; and (2) there will always be (with rare exceptions) adequate stock on hand to fill your order *immediately.*

Merchants find it is good business to be thus equipped to render this service to their customers — quickly, intelligently and accurately — as you, the doctor, demand it. And doctors find it often saves their patients days and weeks of unnecessary pain and discomfort to send them directly to "Headquarters" for their anatomical support. Camp Supports, of course, are sold and fitted *only* through reputable stores — they are never sold by door-to-door canvassers.

Experience is the Best Teacher

Richard Bright *(1789-1858) proved it in anatomy*

Richard Bright, a renowned physician of his time, made many fundamental contributions to medical science. Besides his many brilliant anatomical observations, he was among the first to describe acute yellow atrophy of the liver and to point out that dropsy with albuminuria was the result of kidney disease. Bright's detailed studies still are important additions to the collected experience of medicine.

R. J. Reynolds Tobacco Co., Winston-Salem, N. C.

Experience is the best teacher in cigarettes, too!

YES! Experience counts in medicine—and in choosing a cigarette, too. Thousands and thousands of smokers who have tried and compared many different brands of cigarettes have learned from experience that Camels suit them to a "T." Result? More people are smoking Camels than ever before.

Try Camels! Discover for yourself how the rich, full flavor of Camel's choice, properly aged, and expertly blended tobaccos pleases your taste. See if Camel's cool, cool mildness isn't mighty welcome to your throat.

See for yourself why, with millions of smokers, Camels are the "Choice of Experience."

According to a Nationwide survey:

More Doctors Smoke CAMELS

than any other cigarette

Three independent research organizations in a nationwide survey asked 113,597 doctors what cigarette they smoked. The brand named most was Camel!

Excellent results

IN ORAL ESTROGEN THERAPY

ESTINYL* (ethinyl estradiol) affords "relief of menopausal symptoms with excellent results"[1] in from 87.8 to 100 per cent[2] of cases. On a weight basis, ESTINYL is many times more powerful in estrogenic effect than other natural and synthetic estrogenic agents.[3] It acts rapidly, causing disappearance of hot flushes in 3 to 8 days[4] and often completely controls other climacteric symptoms in 7 to 10 days.[5]

ESTINYL

(ETHINYL ESTRADIOL)

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

is well tolerated, there usually being "complete absence of side reactions if minimal effective doses are administered."[2] An additional asset of ESTINYL therapy is the "sense of well-being"[6] it commonly evokes.

DOSAGE: One ESTINYL Tablet, 0.02 mg., or one teaspoonful of ESTINYL LIQUID daily. In severe cases two to three tablets daily, or their equivalent in ESTINYL LIQUID may be prescribed, reducing dosage as symptoms subside.

ESTINYL Tablets, 0.02 (buff) or 0.05 mg. (pink), in bottles of 100, 250 and 1000.

ESTINYL LIQUID, 0.03 mg. per 4 cc. (teaspoonful), in bottles of 4 and 16 oz.

The Gamut of Nutrients

When the need for dietary supplementation arises, the delicious food drink made by mixing Ovaltine with milk finds wide application. This dietary supplement provides generously of all nutrients considered necessary, in balanced proportion for optimal utilization. Three glassfuls daily, in conjunction with even an average diet, raises the intake of essential nutrients to optimal levels.

Its appealing taste and easy digestibility virtually assure patient acceptance, as well as consumption of the recommended three glassfuls daily.

Ovaltine finds valuable use pre- and postoperatively, following recovery from infectious disease, in pregnancy and lactation, in pediatrics in the management of food-resistant children, and to supplement restricted dietaries whether prescribed or self-imposed as a result of food aversions and idiosyncrasies.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

Ovaltine

Three servings daily of Ovaltine, each made of ½ oz. of Ovaltine and 8 oz. of whole milk,* provide:

CALORIES	669	VITAMIN A	3000 I.U.
PROTEIN	32.1 Gm.	VITAMIN B_1	1.16 mg.
FAT	31.5 Gm.	RIBOFLAVIN	2.00 mg.
CARBOHYDRATE	64.8 Gm.	NIACIN	6.8 mg.
CALCIUM	1.12 Gm.	VITAMIN C	30.0 mg.
PHOSPHORUS	0.94 Gm.	VITAMIN D	417 I.U.
IRON	12.0 mg.	COPPER	0.50 mg.

*Based on average reported values for milk.

EFFECTS OF INFECTIOUS DISEASES AND TRAUMA ON BODY PROTEIN

There are two large groups of disorders which produce generalized protein breakdown: *infections,* acute and chronic, and *trauma.* Infections usually produce fever. A rise in temperature of one degree Fahrenheit means a seven to ten per cent rise in metabolic rate. In addition, bacterial toxins may cause protein breakdown by affecting the cells directly. For these reasons, loss of weight is an outstanding feature of infectious diseases. Diet, especially during convalescence, is therefore high in calories and in the *proportions of protein.* Certain types of injury produce an intense protein *breakdown* which may last for several weeks. The negative nitrogen balance which follows injury is difficult to counteract. *Extremely high protein intakes* are needed to minimize the loss of body tissue.*

SWIFT'S STRAINED MEATS

Palatable protein supplementation for patients on soft, smooth diets

When surgery, disease or trauma creates a problem in protein supplementation, many physicians now use Swift's Strained Meats. These all-meat products provide a palatable source of complete, high-quality proteins, B vitamins and minerals. Originally developed for infant feeding, the meats are strained fine — may easily be used in tube-feeding or for oral feeding in soft diets. Swift's Strained Meats are convenient to use — ready to heat and serve. Six kinds provide variety and tempting flavors that help combat anorexia: beef, lamb, pork, veal, liver and heart. 3½ ounces per tin.

ALSO SWIFT'S DICED MEATS — for high-protein diets requiring foods in a form less fine than strained, these tender, juicy pieces of meat are highly desirable.

Laboratory studies on sperm-immobilizing power and clinical studies on occlusive action and safety establish that "RAMSES"* Vaginal Jelly affords the optimum protection that a jelly alone can provide. For example.

- It will immobilize sperm in the fastest time recognizable under the Brown and Gamble method.
- It will occlude the cervix for as long as 10 hours after coitus.
- It will not liquefy or run at body temperature.
- It does not separate.
- It is nonirritating and nontoxic.

For optimum protection when dependence must be placed on jelly alone, specify "RAMSES" Vaginal Jelly.

Active Ingredients: Dodecaethyleneglycol Monolaurate 5%; Boric Acid 1%; Alcohol 5%.

The Petechiometer* a Rexall exclusive

Rexall

DRUGS

YOU CAN DEPEND ON ANY DRUG PRODUCT THAT BEARS THE NAME REXALL.

The Petechiometer—exclusive with Rexall—is a new device used in the measurement of capillary fragility. It is a simplification of the suction-type resistometer used in the Dalldorf test.

A small suction pump with a spring-returned plunger and clear plastic suction cup, the Petechiometer applies negative pressure to a hairless area of skin two centimeters in diameter. A magnifying glass blown into the upper surface of the cup helps count petechiae which develop.

The air is expelled from the suction cup by pressure of thumb on plunger. The cup is then placed lightly but firmly upon the skin. As thumb pressure is released, spring action applies suction. After one minute, suction is released; after five minutes, petechiae are counted. By moving an adjustable "stop" ring the test may be repeated at two additional suction levels. Remember that increased capillary fragility is a complication of many clinical conditions.

You can obtain the Petechiometer only at drug stores displaying the familiar blue and white Rexall sign—your assurance of drugs manufactured under rigid laboratory control, compounded with superior pharmacal skill. Your Rexall druggist will be glad to tell you more about the Petechiometer. Or write to Rexall Drug Company, Los Angeles, California.

**Petechiometer is a registered trade-mark owned by the Rexall Drug Company covering a clinical device for the measurement of capillary fragility.*

PHARMACEUTICAL CHEMISTS FOR MORE THAN 45 YEARS

There'll be fewer sleepless nights this season

BY JULIO DE DIEGO

THE INTRODUCTION of Abbott's new antihistaminic, THENYLENE Hydrochloride, means that more allergic persons than ever before will be working, playing, sleeping in greater comfort. Some hay fever patients will be symptom-free; others will experience relief to a lesser degree. Side-effects will be limited.

In a series of 112 patients with seasonal hay fever (including pollinosis caused by trees, grass, weeds and molds) it was reported that 70 percent were benefited following treatment with THENYLENE Hydrochloride. From a number of independent investigators come reports on various allergies treated with THENYLENE: in a total of 695 such cases, 67 percent were benefited. A significant number of patients in one test group who received several different antihistaminics, reported a better tolerance for THENYLENE, with fewer side-effects.

While no harmful effects have been reported, a total daily dose exceeding 400 mg. (0.4 Gm.) is not recommended, nor continuous use of the new drug beyond eight weeks.

If you would like to try this new antihistaminic, just drop a line to Abbott Laboratories asking for your professional sample and descriptive literature. Or ask your pharmacist—he has THENYLENE Hydrochloride in sugar coated tablets of three sizes, 25 mg., 50 mg. and 0.1 Gm. in bottles of 100, 500. ABBOTT LABORATORIES, North Chicago, Ill.

Nu-Trend

● A NEW, BEAUTIFUL WOOD SURGICAL SUITE....BY HAMILTON

The latest addition to the Hamilton line, this new and beautiful suite of matched woods is designed to create new warmth and beauty for your examination room. Patients appreciate its modern distinctive appearance. It is economically priced and designed to help make your work more pleasant.

Available in a choice of two woods and four finishes, each designed to create a different effect. Selections may be made from red mahogany with tan upholstery, blonde mahogany with tan upholstery, regular walnut with brown upholstery, or silver gray walnut with burgundy upholstery. Features consist of a large examining chair-table with counter balanced top, adjustable stirrups, Hide-A-Roll attachment, steel-wood drawers, concealed treatment feature and generous storage space. The roomy instrument cabinet is available with either solid or glass doors.

THE NEW LOOK IN MEDICINE

A. E. CARDLE, M.D.
Minneapolis, Minnesota

GEORGE BERNARD SHAW once made the typical Shavian statement that "The ice of life is slippery." It seems to me that this statement has more than ordinary significance for the great social order of medicine. The road of medical practice throughout the ages has had the same characteristics as Shaw's "Ice of Life"—hard-cold —slippery. It has consistently been a difficult road. The reception of the lay public has often been cold. And right at this point in history, I dare say, the medical practitioner, whether he realizes it or not, faces a set of circumstances which are the most slippery that have ever confronted his profession.

Tonight we need not be too concerned about the hardness of the road, for worthwhile achievement in any line has always been attained at the price of hard work. No physician who is worthy of the name has any unwillingness about paying the price, in terms of hard work, which his calling demands. We likewise need not be too concerned about the cold skepticism which in the past has often greeted our efforts in the realm of medical research. Broader education has brought the lay public to the realization that such research is essential to its own personal well-being. However, tonight I do wish to talk to you about the currently ice-like situation which confronts us in medicine—the slipperiness underfoot as we move ahead on a path filled with greater responsibility than medical men have ever before faced. That path, according to our own choosing, can lead to higher levels of medical achievement and human welfare under professional initiative, or it will retrogress to a level of enforced mediocrity.

The direction in which our profession moves along this path is largely dependent on what you and I as individual physicians do—not one year, five years, or ten years from now, but tomorrow and the next day and every day. Let us take stock, therefore, of the assets at our disposal, which we must utilize to the fullest if we are to have public opinion firmly on *our* side instead of having it flirt with government-dominated medical care.

Without question the Number One asset of today's medical man is the personal and professional respect which he commands. Every one of us here tonight possesses a generous measure of that asset. Over the span of our careers it is far more valuable than stocks, bonds or bank balances. This respect springs from a variety of sources. Self-sacrifice is one of them. The country doctor who made his rounds in a horse-drawn buggy in bitterest weather had a tremendous reservoir of respect in his local community. We are out of the horse and buggy days now, but countless doctors who daily demonstrate similar devotion to their calling and an equal measure of human kindness have just as great a backlog of respect. Education is another source of this respect. Today when bachelor's degrees are becoming commonplace, the doctor of medicine continues to advance to an ever-higher plateau of learning which not only enables him to keep pace with increased demands of his profession but enlarges his potentiality for community leadership. Confidence is another wellspring of respect.

Presidential Address, read at the annual banquet of the Minnesota State Medical Association, Minneapolis, Minnesota, June 8, 1948.

Basically, I believe the confidence of the layman in the physician represents a confidence in the standards of professional medicine. As the physician discharges his responsibilities in keeping with those high standards, he is automatically an heir to the respect which stems from the public's confidence in the profession as a whole. I could name other sources of this invaluable asset of public respect—they are too numerous to mention, and each of us has his own personal store of them. One which has reflected lasting credit on the profession as a whole is the magnificent humanitarianism and selflessness displayed on the battlefronts of the late war by many members of our group.

Now assets, whether they be of the tangible type found in the world of commerce, or of our own less tangible kind, are valuable only to the extent that they are put to proper use. And what a challenge we medical men face today to put our assets consciously and boldly to work to promote the public welfare by promoting the things for which we stand! Let's look for a moment at the factors which today demand that we put these assets to work if our ability to serve is to go unimpaired.

First of all, we all recognize that the same forces which have materially altered the social order during the past several decades, and which more than ever before have increased the importance of the individual citizen, have likewise brought about significant changes in the attitude of the citizen toward his doctor. These forces and the attitudes which they create are at work in both directions, that is, doctor to layman and layman to doctor. Just as today's age of speed makes obsolete the old horse and buggy mode of operation, so it places new and ever-greater demands on the modern doctor. He must cover more ground, minister to more patients, and at the same time keep abreast of accelerating scientific advancement. Because even we doctors are human, it is only natural that oftentimes our daily services are rendered more hurriedly and with a less personal touch than in days past. We are likely to forget that the individuals with whom we deal by the score are just as human and just as desirous of receiving adequate personalized attention as were the patients of yesteryear with whom the doctor dealt leisurely in ones and twos.

On the other hand, the layman of today has evolved into a creature more *inquisitive* and more demanding of his physician than patients ever before have been. The modern American mind is also extremely receptive to emotional appeals, which fact in no way makes the doctor's job any easier. One result is that public attitudes tend to be strongly influenced in favor of the side which gets its story across more clearly and more completely, assuming, of course, that the story is a good one. This emotional influence cannot be ignored in the physician's daily scheme of operation.

By this time you may be thinking: "Well, what does this have to do with me? Don't tell me this fellow is going to start advising me how to run my practice!"

Fortunately, no. That would be impossible even if I wished to do it, because, thank goodness, the medical profession is still a stronghold of unfettered intelligent initiative. But—let us right here and now resolve not for a single minute to lose sight of the fact that the sum total of the daily conduct of our individual practices is entered on the debit or on the credit side of American medicine. Your relations and my relations with our respective clients help to make or break the ability of medicine to continue performing a high calibre of service for the American people and for the world.

Let us not for a minute delude ourselves with any notions of a public which over all is deeply thankful to us for work schedules which include long, irregular days and fatiguing, interrupted nights. A common notion is that the doctor is seldom immediately available because he is forever running around enjoying all his leisure time. Let us not be complacent in the satisfaction that the statements we tender our patients at the end of the month generally represent excellent value received because *we* know the toil and the concern which have gone into our ministrations. The patient has been told repeatedly by certain groups who take pains to get into public print that he is being cheated. Now he is beginning to believe it. (Why shouldn't he? No doctor has ever told him anything to the contrary!) And let us not be too gratified by the fact that we recognize today's superior medical service is possible only because the American procedure is established upon the bedrock of scholarliness, integrity and sound achievement. How *we* feel about our profession is important, but how *the public* feels about us is of even greater significance.

Right now the cold, blunt facts are that, despite its heritage of remarkable achievement, American medicine—and that means you and me, who are a part of it—is facing the severest kind of criticism which, if unanswered, promises to lead to consequences that will inevitably be regrettable and inimical to the welfare of American society.

I hope you won't misunderstand me. When I imply that our critics should be answered, I do not mean that American medicine should go on the defensive. American medicine does not have to go on the defensive. What it does have to do is to take out from under the bushel the light which will reveal that modern medicine is more than just alive and kicking. That it has a heart and soul. It is imperative as I see it that we medical men merchandise our assets to the end that our profession is unquestionably allied with the public interest—so that our endeavors and objectives will be readily recognized by the average citizen as being identical with his health and welfare, and duly considerate of his pocketbook.

One sure avenue in that direction is to drop some of our unwarranted reticence. We must stop looking at ourselves for a change and begin looking at the other fellow who makes up our clientele. We must get on somewhat more common ground with him, in our attitude, in our language, and in the small amenities of everyday business, which he will appreciate, and which are certain to redound favorably to us in our growth in the profession.

Let me report one or two current criticisms which I believe are fairly typical: A few days ago a friend of mine was heard to say, "It has been my experience that the better qualified a doctor is professionally, the less inclined he seems to be to spare even a reassuring word of sound information to his patients. Frankly, I pay my fees to my doctor for something more than simply to hear him grunt when I ask him a reasonable question." In days gone by when public curiosity was less keen and the physician's word represented unquestioned authority, the doctor's "grunt" was somewhat more passable, if no less ill-mannered. Today, however, it connotes just one thing—a public-be-damned independence which insults the patient's dignity. One thoughtless doctor multiplied by one patient who has been slighted can work untold ill toward the professional cause of all of us. If many doctors the country over indulge in this single expensive luxury of abruptness, the equation reaches astronomical proportions.

Not that a successful medical practice depends on devoting a large portion of our time to pampering prima donna patients. But, somewhere there always exists a middle ground, a happy medium in human relations which it is part of the intelligent doctor's job to detect, and to apply.

Here's another increasingly common criticism: A couple of weeks ago an executive of a large corporation, a man in good circumstances, was irritated because his daughter's overnight stay in a hospital following tonsillectomy had resulted in what he considered a greatly excessive charge. Whatever the justification for this charge, it came as a shock to this person of good means. We can only assume it would have been nothing short of staggering to the average working man. Does such a situation disturb you? It does me, because in the mind of the lay public the distinction between medical and hospital expenses is practically non-existent. If anything, the cost of hospital care is associated with the physician himself and he is given the blame if that cost seems exorbitant. I venture that there is no one here tonight who has not suffered some blame because the medical world has failed to hammer home this distinction.

Let us not underestimate the mounting public feeling over this situation. While hospital costs are a factor not readily controllable by physicians themselves, the reflection which they are currently casting upon our profession behooves us to give serious consideration to a clear-cut public explanation of these costs and the reasons why the doctor is not to blame for them (except in the injudicious use of expensive laboratory procedures). I have yet to see a situation where the public, if given the facts in understandable language, does not respond with sympathetic understanding, which in this instance would be of untold benefit to us.

The formidable accumulation of circumstances coming to bear on modern medical practice from all directions is not unlike a snowball gathering both bulk and momentum as it rushes down hill. This combination of circumstances sets the stage of public opinion for a medical panacea which promises something twice as good at half the cost or less, just as surely as the stage was set a couple of decades ago for economic panaceas

which would free the populace from the humdrum drudgery of earning a living and paying taxes.

"Well and good," you may be saying. "If that's the case, why not just sit tight and let nature take its course? After a while things will return to normal and the pressure will be off. Why get excited?"

I hope that not too many doctors are viewing the situation that way. Those who do are, in my opinion, letting their professional obligations and their future go by default. For one thing, it is idle to look for a return to "normal" in the sense that prewar medical practice was normal. Medical science has received its own dose of jet propulsion during the past six or seven years and it promises to keep all of us moving faster in the discharge of our duties throughout the foreseeable future. If the medical schools continue to produce graduates at the present rate and if Uncle Sam becomes more liberal in the release of medics now in the armed forces (which at present seems more unlikely than ever), we might without too much difficulty be able to maintain a constant level of satisfactory service to all clients desiring it. That is—if the proportion of the population needing such services were to remain constant. But—the growth of geriatrics is enabling more and more people to reach the age brackets where the incidence of ill health places a proportionately greater strain upon the medical services. Whereas in 1900 only 3,000,000 U. S. citizens were over sixty-five years of age, in 1940 there were 9,000,000, and under present trends it is estimated that in 1960 there will be 14,000,000, and in the year 2000 there will be 21,500,000 over the age of sixty-five.

To some this trend might be a clear-cut case for government action. But, a great many of your friends and mine will be among those 14,000,000 who in 1960 will be sixty-five or older. Those people are no less human and no less deserving of the high calibre service which American medicine has been accustomed to give than are those who are sixty-five today. As great as is the challenge presented by this expanding need for medical service, I do not believe it is too great for our combined abilities, any more than I believe that it can be satisfactorily met through some mysterious pushbutton planning. On the contrary, it seems to me that this challenge calls for the prompt, continuous, logical application of those assets which we have in ample store but which we have by custom failed to exploit fully. Hard work will not be enough, although there will be plenty of that. Equally important will be a purposeful dedication of our thoughts and energies toward more efficient, common-sense means of performing our duties, to the end that the greatest possible service will be rendered to the greatest number at a cost which may readily be regarded as reasonable.

Admittedly this is an ideal. But it is not an ideal in the sense that it is far beyond attainment. We *must* attain someting approximating this and we must periodically make public our progress toward this attainment if the privilege of aiming at this goal is to be left in our hands. This challenge for greater service will not be met by pronouncements from public platforms. It will not be met in the medical convention halls. It will not be met in the technically phrased trade journals. It can be met only by you, the doctor on the home-town firing line, working as an individual professional man and in concert with doctors the country over as a member of a socially conscious medical fraternity.

It is not too much to say that your every social and professional word and act can be a valued enlistment in this cause. But to do so it must be consciously geared to the new look in medicine which calls for closer harmony and more mutual appreciation between doctor and patient, between doctor and layman, between doctor and business man, between doctor and civic leader, between doctor and editor.

Every one of us has his own traits and his own circumstances with which to cope, so it is unwise to be too dogmatic or to rely on a pat formula by which we may be guided in making our individual contributions toward meeting today's challenge to medicine. But in these closing moments I cannot help but pass along to you a few simple "fashion hints." To many of you these may sound as old as the bustle or the hoop skirt, but they are definitely a part of the "new look" in medicine which is called for by these times:

Let us get better acquainted with men in occupations unrelated to medicine, and enable them to take a closer look at us. The doctor whose presence at a social function consists of sitting off in a corner talking shop with another doctor may be adding in a small way to his knowledge, but he is losing out in a big way on the oppor-

tunity to let others in the groups outside of his profession get a better appreciation of medical science and the men who are engaged in it.

Let us polish up our good citizenship. An "M.D." should be the hallmark of leadership in the eyes of every layman, and many a doctor is living up to that leadership, although too often it is confined to purely medical projects. Too many doctors still regard civic, educational and social service endeavors either "a little out of their field" or "too demanding on their time." We cannot arouse public enthusiasm for our cause if, in the limelight of the professional arena, we dodge our civic responsibilities.

Let us avoid long-hair phraseology which suggest that we are hiding behind a cloak of technical knowledge. Many a patient would feel he is receiving more satisfactory treatment if common one and two syllable words were substituted for medical mumbo-jumbo he cannot understand.

Let us make a conscious effort to be visibly interested in our patients as personalities. Our manner should clearly indicate that their problems are our foremost concern of the moment. It is time we doctors stopped making laymen discount our attitude toward them with such observations as, "Well, Dr. Jones is a busy man and deeply absorbed in his work. I suppose that's what makes him a little peculiar."

Let us wear a friendlier smile. I do not mean that every doctor should have a petticoat of white teeth showing beneath the hem of his upper lip, but a sincere smile that springs from within can do more to set a patient and his family at ease—and again to make him feel satisfied that he is getting valuable personal attention—than can any recitation of formidable medical facts.

Let us give more credit when and where credit is due. To my knowledge, no doctor has ever hurt his own reputation by publicly praising outstanding work of another doctor. There is reason to believe that a little more of such justifiable praise would do much to allay the common misconception that medical men are split by wide personal differences and jealousies.

Let us take a more active part in the efficient operation of our hospitals. The public will sympathize with us when we explain that high hospital costs do not originate with us, but they will not excuse us from the responsibility of working to keep those costs down and to make adequate hospital care financially possible for broad segments of the citizenry.

Let us keep abreast of national affairs and national policies, particularly as they affect medicine.

Let us determine to gauge all our actions by their potential effect on our clients and on the public. Only then can we expect that the public will vigorously agree that medical men still know more than anyone else how to run their own business. Complacency and aloofness must give way to agreeableness, aggressiveness, sociability and well-mannered salesmanship.

These represent just a starter. Many of you are already ahead of me; you are analyzing your own situations and adding more precepts which these situations suggest. As I visualize the great reserves of energy, ideas, brains, skill and humaneness on which American medicine, as symbolized by yourselves, can draw, I cannot help but feel that the impending challenge will be met. I feel certain that meeting it will bring out the best that is in us. And I believe that the story of our preparedness and determination to meet that challenge will merit the kind of respect that will clear the ice from underfoot, and permit American medicine to continue forward on a solid path of public appreciation and public approval.

HOSPITAL CONSTRUCTION ACT PROGRESS

Progress under the Hill-Burton Act (Public Law 725) is far better than most proponents of the Act expected. Only six months have passed since approval of the first project, yet (July 1) 347 projects have been approved in forty-two states. Also contrary to expectations, the program is reaching into areas really in need of additional facilities.

The picture on May 15, 1948, was as follows (July data not available): forty-six states and territories have state-wide plans approved; 39 million dollars are involved in 272 construction projects approved in thirty-one states. The 272 projects include: 244 hospitals, 23 health centers, and 5 auxiliary facilities.

Most of the 212 proposed general hospitals are under 50 beds: Under 25—51; 25 to 50—76; 50 to 75—52; 75 to 100—10; 100 and over—23.

Most of these general hospitals will be located in rural communities: 93 in towns under 2,500 population; 47 in towns 2,500 to 5,000 population; 35 in towns 5,000 to 10,000 population; 23 in towns 10,000 to 25,000 population; 4 in towns 25,000 to 50,000 population, 10 in towns 50,000 population and over.—News Letter, Council on Medical Service, A.M.A., Vol. V, No. 6, July 22, 1948.

PRACTICE OF MEDICINE IN RAMSEY COUNTY

JOHN M. CULLIGAN, M.D.
Saint Paul, Minnesota

FIRST of all, I wish to express my sincere gratitude to the members of the Ramsey County Medical Society for the honor conferred upon me by electing me your president for the year 1947. I have enjoyed the year tremendously and have received wholehearted support and assistance from the entire membership of the society, particularly the members of the various committees. It has been a novel and interesting experience for me, and I want you all to know that I am sincerely proud to have been able to serve as your president.

It often has been said that Ramsey County is one of the most enjoyable places to practice medicine because of the spirit of good fellowship and comraderie that exists among the members of the profession. It is my privilege as your retiring president to recall to the minds of some of the older members of the society the factors which have brought this situation about and to acquaint the new members of the heritage which is theirs. This situation is something which should not be allowed to die, as it makes for the happiness of the members of the profession and indirectly aids the quality of medicine in this community. Our new president-elect, Dr. J. Richard Aurelius, expressed succinctly this sentiment by saying, "If I could only eke out an existence practicing medicine in Saint Paul, I would prefer it to any other community even though the monetary returns were much greater elsewhere."

The Ramsey County Medical Society has been the guiding organization of the local profession now for seventy-seven years. This society as we know it today was formed on February 14, 1870, and incorporated later in that year. The purposes of the society are expressed in its constitution as follows: "Its general purposes shall be to contribute to the development and advancement of the science and art of medicine and medical education; to promote the public health; to encourage and foster a spirit of fellowship and co-operation among its members; and to maintain the ethics of the medical profession, to the end that it may enjoy the respect and support of its members and the community."

Presidential address presented to the Ramsey County Medical Society, January 26, 1948.

The first officers of the society were Dr. Daniel W. Hand, president; Dr. Alfred Wharton, vice president; Dr. William Banks, corresponding secretary; Dr. C. H. Boardman, recording secretary; and Dr. Samuel D. Flagg, treasurer.

The organization of medical societies in Minnesota had rather hectic times until the Minnesota State Medical Association was formed February 1, 1869. It was through the efforts of this association that the local county societies in the state were organized, and they have been on a satisfactory basis ever since. That is why the Ramsey County Medical Society, as we know it now, was organized February 14, 1870. Preceding this, in 1853 the Minnesota Medical Society had been formed. It was reorganized in 1856 and languished and died, the last meeting having been held in 1857 in St. Anthony, as Minneapolis was then called. The Saint Paul Academy of Medicine and Surgery was formed in 1860 and incorporated in 1861. This lasted a few years and languished possibly because of the intervention of the Civil War. The Minnesota Homeopathy Institute was formed and incorporated in 1867. The State Medical Society for Eclectic Physicians of Minnesota was formed in 1869. This lasted only a very short time. The Saint Paul School for Medical Instruction was organized in 1870 and was under the direction of Dr. Alexander Stone. This proved to be a very flourishing organization for a great many years.

The first physician to actually locate in Saint Paul for the practice of medicine was John Jay Dewey. He arrived July 15, 1847, when Minnesota was still a territory and had not been admitted to the Union as a state. Previous to this time the only physicians in Minnesota were those stationed at Fort Snelling, who sometimes rendered medical services to some of the residents of Saint Paul in addition to caring for the personnel at the army post. The first army surgeon arrived in 1821. He was Edward Purcell. He was called frequently to attend residents in and around the surrounding country. He died in 1825. He was followed by a surgeon named B. F. Harney and an assistant surgeon named Robert C. Wood in 1835. Reverend Thomas S.

Williamson, M.D., arrived to attend to the spiritual and physical welfare of the post and its environs. He remained at Fort Snelling until 1851 and performed the first marriage by a clergyman in Minnesota Territory. It is interesting to note that surgeon John Emerson, while stationed at Fort Snelling, was the owner of the celebrated negro slave, Dred Scott, whose case involving ownership went to the Supreme Court of the United States. The decision rendered by Chief Justice Roger Brook Taney was a major factor in precipitating the Civil War.

Due to the inability of the post physicians to attend the growing community, most obstetrical cases were attended by midwives who were very numerous in the community. The community was not at all times called Saint Paul. It was known by various names principally Kaposia, Pig's Eye (after Pierre Parrant), Saint Paul's Landing, Saint Paul's, and finally Saint Paul. By 1849 the number of practicing physicians in Saint Paul had increased to five. The first records of deaths were reported June 1, 1850. There were fifteen deaths reported, one individual having attained the age of eighty years. The average age of the fifteen was 20.04 years. It is certainly an excellent compliment to the efforts of the medical profession that today the life expectancy of a child born in Minnesota is sixty-four years. By 1853 ten physicians were in Saint Paul, and in 1860 twenty-seven were practicing here.

In 1853 the first hospital in Saint Paul was started. St. Joseph's Hospital under the direction of the Sisters of St. Joseph opened its doors in 1854. St. Luke's Hospital was opened in 1873 under the direction of the Episcopalian Church. However, preceding this, in 1855 the Christ Church Orphan's Home and Hospital were incorporated. This was the forerunner of the present St. Luke's Hospital. In 1882 Bethesda Hospital was opened under the direction of the Lutheran Church. They remained in their first quarters until 1932 when the present new hospital was opened to the public. In the same year, 1882, the City and County Hospital of Saint Paul was opened. This was long under the direction of Dr. Arthur B. Ancker, and following his death the hospital's name was changed to Ancker Hospital. In 1906 Midway Hospital was opened in modest quarters. Mound's Park Hospital was opened in 1907. These were both under the direction of the Baptist Church. The new Midway Hospital was opened in 1928. St. John's Hospital followed in 1910, and this was also under the direction of the Lutheran Church. In 1911 Gillette Hospital was opened. Since 1897 the crippled had been cared for at the City and County Hospital. With the opening of the Gillette Hospital, crippled children were transferred to this state-operated hospital. In 1913 West Side General Hospital was opened, and this has no direct religious affiliation. In 1920 through a gift of Charles T. Miller, the Miller Hospital was opened. In 1921 the Northern Pacific Hospital was moved from Brainerd to Saint Paul, and it has operated under the direction of the Northern Pacific Benefit Association for the welfare of the railroad's employes. In 1928, through the tireless efforts of Dr. Walter Ramsey, a large enough sum of money was subscribed by people of Saint Paul to build and endow the Children's Hospital. All through the years these institutions have served the public in rendering medical care. They have kept pace with the new developments in medicine and surgery and in all this time have rendered care second to none in the country.

In Saint Paul's medical history numerous epidemics have swept the community. In 1847 and in 1848 what was called miliary fever became very widespread and attacked mostly the young adult population. From the description of the disease, it was undoubtedly an epidemic of scarlet fever. Three epidemics of Asiatic cholera swept through Saint Paul. These were described by Dr. John Armstrong.[1] In 1847 and 1848 a few cases were reported among the arrivals on boats coming from Galena, Illinois, and New Orleans. This epidemic never became very widespread, but in 1855 an extremely widespread epidemic broke out. Every boat arriving brought new cases, as persons were becoming infected on the boats due to drinking impure water. The mortality is not known but deaths were very rapid after infection. Much fear of the epidemic existed throughout the population, and when it was decided that St. Joseph's Hospital was the best place to take care of those infected with cholera, a mass meeting was held at Timm's Grocery Store at Ninth and St. Peter Streets, and the Sisters were warned that if they brought cholera into that neighborhood the hospital would be burned. Also an indignation meeting was held on the West Side when a pest house was proposed

in that neighborhood. However, shortly after this, the epidemic subsided, to recur again in 1866 but only for a short time. The newspapers carried very little concerning the amount of cholera present in the community during these epidemics, as they were afraid it would deter the immigration of people to this thriving community. In fact, frequently the presence of cholera was denied.

In 1861 an epidemic of hydrophobia appeared. Dogs apparently infected in the southern part of the state transmitted the disease here, with the result that all dogs were ordered destroyed and the epidemic ceased.

In 1884 a smallpox epidemic developed, and widespread vaccination was promulgated. As an example to the community, all the Sisters at St. Joseph's Hospital underwent vaccination, except one Sister who hid when her turn came to be vaccinated. She contracted smallpox and was the only member of the religious community who died. On her death bed she pleaded with others not to neglect vaccination.

In 1918, 1919, and 1920, the pandemic of influenza swept the country, including Saint Paul. Practically all the hospitals in the city were turned into influenza hospitals, and the mortality was terrific. It will be interesting to note whether in the next two years an epidemic of influenza will recur, because they have occurred every thirty years for practically as long as medical records have been kept. If we are going to have a recurrence of this epidemic it should break out within the next year or two.

All during this time, typhoid fever was practically always present.

In the early years, articles by physicians in this community were published in numerous journals, principally the *Northwestern Medical and Surgical Journal,* published in Chicago; the *New York Journal of Medical and Collateral Sciences;* and the *Cincinnati Lancet and Observer.* The first medical journal to appear in Minneapolis was the *Minnesota Homeopath,* published in 1854 by George Hadfield.

From 1889 to 1913 the Ramsey County Pathological Laboratory was conducted by the Ramsey County Medical Society. This was discontinued in 1913 because of the formation of pathological laboratories in all the various hospitals.

The Ramsey County Medical Library received its start principally through the efforts of three individuals, Dr. Edouard Boeckmann, Dr. H. Longstreet Tayor and Dr. John Rothrock. The library now contains more than twenty-nine thousand volumes, and is as fine and complete a county medical library as there is in the country. The library has been supported from different sources. In 1899 it was supported by voluntary subscriptions from its members, from the proceeds from the *Saint Paul Medical Journal,* and from an appropriation from the Pathological Laboratory Committee's profits. After the discontinuance of the Pathological Laboratory, the library was supported by appropriation of society funds. The greatest financial support of the society has been derived through the benefaction of Dr. Edouard Boeckmann. He invented and developed Pyoktanin catgut which he manufactured for his own use and that of his colleagues. Through his generosity he contributed this catgut industry to the Ramsey County Medical Society, and it is still being made in the Ramsey County Society rooms on the sixteenth floor of the Lowry Medical Arts Building. Although it is not making much money now, it is at least staying out of the red. However, this business has flourished in the past, and the result of this, the Ramsey County Medical Society is undoubtedly the wealthiest county medical society in the world.

The accumulation of the so-called building fund had rather an interesting beginning. In 1901 the American Medical Association met in Saint Paul for the second time. A subscription was taken for entertainment of the visiting physicians, and after the convention there was a balance of $3,000. This was guarded by Dr. Charles Wheaton and later given to the Ramsey County Medical Society as the nucleus for a building fund. To this original fund was added profits from the *Saint Paul Medical Journal* and from the catgut industry, so that now the Ramsey County Medical Society building fund amounts to $256,051.94 which is held in bonds and stocks. The income from this amounts to $10,812.05 per year. From this income about $6,000 is contributed to the library to help maintain the acquisition of periodicals and medical books. This is augmented of course by moneys supplied from the annual dues of the members.

Also housed in the library is a museum of old instruments and medical gadgets, as well as a small number of old medical books. This was accomplished through the tireless efforts of Dr.

John Armstrong, and it was through his efforts that most of the historical data which I am presenting here to you this evening were preserved.[2]

Several noteworthy events in medical history have occurred in Saint Paul. In 1886 Dr. Justus Ohage, Sr., father of our own Justus Ohage, performed a cholecystectomy in St. Joseph's Hospital, the first ever to be performed in America. Probably the first, but at least the second, bronchoscopy was performed by Dr. Arnold Schwyzer. There is some controversy whether he or Coolidge of Boston performed the first bronchoscopy in America. Dr. Schwyzer had just returned from Europe and had brought a bronchoscope back with him. While he was unpacking the instrument, he got a call from a patient who had a bone lodged in his trachea. He performed a tracheotomy and removed the bone by means of the bronchoscope. This was in the fall of 1904. He was assisted at the operation by Dr. Fred C. Schuldt.

Our own Fred Plondke, while visiting in France in 1906, received about fifty ampules of stovaine from a French chemist and performed a large number of surgical cases under spinal anesthesia on his return home in 1906 and 1907. I believe this was the first time spinal anesthesia was ever performed in America. I do not know whether Dr. Plondke experienced any untoward results from spinal anesthesia, or whether he simply stopped using this anesthesia because he ran out of stovaine.

Another off-shoot of the Ramsey County Medical Society is the Ramsey County Medical Foundation, Inc. This foundation was founded and incorporated November 23, 1938. Every member of this society is automatically a member of the Ramsey County Medical Foundation. Its purpose is to aid indigent physicians and their families. The organization was brought about as the result of the following incident recorded as follows: "Not long ago a respected Saint Paul Physician died penniless in Ancker Hospital. The irony in this instance lay in the fact that this man had himself established an important service at Ancker Hospital. He had headed the service for many years, and it would be difficult to estimate with any accuracy, at this date, how many thousands of dollars worth of skilled medical service—his only capital and stock-in-trade—he had given, without any return whatsoever except the satisfaction of suffering relieved and a duty performed for the sick and needy of Saint Paul and Ramsey County. It is sad that during his last year, he, too, joined the throng of the stricken, but neither the city which he had served so well nor even his professional colleagues found a way to come to his aid."

That incident and some others, equally sad and equally unnecessary, led to the formation of the Ramsey County Medical Foundation, Inc. This foundation was designed expressly to receive funds from other physicians, from their friends and from organizations (both public and private) which they had served, and then to distribute the income from these funds when the need should arise. It will be distributed through the instrumentality of the foundation to just such men as the physician who died at Ancker Hospital, and many another whose practice has dwindled and whose resources are gone, or to the physician's widow or some other dependent left without means.

Many a more fortunate colleague or his wife have wished for such an institution to which they could make a bequest out of their own plenty. Many a grateful organization—recipient of medical service for which the individual physician would accept no pay—has wished for such an institution to which a gift could be made in recognition of the faithful service of its volunteer staff. Many a public institution which has received thousands of dollars worth of service from Ramsey County physicians would gladly have allotted a contribution as part of its regular budget for such a cause, if there had been a legally constituted corporation which could accept the contribution. There has been no such legally constituted body. The Ramsey County Medical Society, to which the majority of qualified physicians belong, was organized for purposes of scientific advancement and cannot accept such funds. It was clear to leaders in the society, however, that a way must be found. A committee of members was appointed to study the matter and see what, if any, instrument could be created which could receive and disburse aid for needy colleagues and their dependents. So the Ramsey County Medical Foundation came into being.

Another activity of the Ramsey County Medical Society at the present time is the development of a blood bank for the benefit of all the members of the profession and their patients. This

is being worked out with the American Red Cross, so that all types of blood and blood derivatives, such as plasma and Rh positive and negative bloods, will be available at all times. If this plan goes through, anyone can get all necessary blood for merely a nominal charge of about $3.00 if he replaces blood taken from the blood bank. Otherwise a larger fee of approximately $25 will be charged. At the present time between 500 and 600 pints of blood a month are used in Saint Paul. This no doubt would be doubled or tripled if enough blood were available.

I have tried to outline to you some of the history pertaining to the practice of medicine as it has existed here since 1820—some of the problems surmounted, some of the institutions developed, some of the activities of the society and individual members of the society who have made medical history—and I hope I have proved the point that Saint Paul has been a wonderful place to engage in the practice of medicine. That this situation still exists is in no small degree due to the remarkable degree of good fellowship, comraderie, consideration and honesty by a very high percentage of the members of the profession. To the younger members of our group, I hope it will not appear presumptuous of me to give a few words of advice.

1. Continue your medical studies, by the reading of medical literature, by attending medical meetings, by association with other physicians and by attending postgraduate courses, so as to keep abreast of medical progress.

2. Be neat and clean in appearance.

3. Be tolerant to a high degree. Remember you are dealing with human beings, and it takes all kinds of people to make a world.

4. Try to develop a mildly humorous attitude, because the physician who pleases his patient has learned much about the art of medicine.

5. Be the first to suggest consultation, particularly before the patient or relatives do, because in this way they will have greater respect for you instead of becoming doubtful or skeptical.

6. Associate yourselves with other physicians socially and professionally, particularly the older well-thought-of members of the profession, for they are frequently able to give you sound advice on how to avoid pitfalls which have beset them; and the corollary that goes with this—avoid the physician who has obtained his practice unethically.

7. Strive to co-operate with your medical confrére and never criticize your competitor and never believe what a patient tells you the other doctor says. Backbiting and slander only lead to bitterness, hard feelings and malpractice suits.

8. Associate yourself with an accredited hospital.

9. Keep the control of medicine in the hands of the profession, and do this by legislation if necessary. Do this above all if you are interested in the private practice of medicine as distinct from socialized medicine. Maintain the doctrine of free choice of physician by the patient. Do not allow the practice of medicine to be taken over by social service workers, politicians, cultists or racketeers.

Now there is one subject which I feel should be mentioned, and I do so with a little hesitancy and trepidation. That is the chasm which has threatened to widen between the general practitioner and the specialist. I feel, however, that bringing the question out into the open may result in clearing up some of the misunderstandings that have developed. Progress and change are inherent in medicine. If when I took my senior examinations in the medical school, I had answered in the light of what we now know, I would have been ignominiously flunked. So in any profession which develops greatly, certain men must of necessity perfect themselves in a limited field.

This has led to the development of specialties and specialists. The specialists have developed their own local societies and groups, and it is only recently that the general practitioners have formed a society of their own. I think it is too bad that this society of general practitioners was not organized many years ago, for I think it serves an admirable purpose. The general practitioner has just as many problems to solve and discuss as any specialist, and a forum where this can be done is advisable. However, the main cause for complaint on the part of general practitioners seems to be the fear of their exclusion from the hospitals. In 1946 Dr. O. J. Campbell,[3] then president of the Hennepin County Medical Society, canvassed all the Minneapolis hospitals, and this year I interrogated representatives of all the hospitals in Saint Paul, and I can say definitely that there is no inclination on the part of any of the authorities in the Twin Cities' hospitals

(Continued on Page 911)

BRAIN TUMORS IN CHILDREN

LYLE A. FRENCH, M.D.
Minneapolis, Minnesota

THERE have been numerous reports in the literature concerning brain tumors. Except for those of Bailey et al,[1] Ford,[7] Globus et al,[9] and Zülch,[16] few of them have been limited to the tumors occurring during childhood. This fact is surprising, inasmuch as the frequency, the type of tumor, the location and the clinical course in the two age groups, childhood and adulthood, are not at all similar.

Recently, all brain tumors occurring in children of sixteen years of age and younger which were seen at the University Hospitals from June, 1931, to July 1, 1946, have been reviewed. During this fifteen-year period, a diagnosis of brain tumor was made on 202 children. Because of lack of information concerning the clinical course, thirty-one of them are not included in this report. Another twenty-five cases are excluded because of lack of histological verification of the diagnosis. The remaining 146, then, represent only the histologically verified tumors in children in whom complete clinical data are available. In this report, the frequency, location, and histological types of the brain tumors seen in these 146 children will be discussed first, after which the symptomatology and roentgenography will be reported.

Frequency.—There were 819 verified brain tumors during this same fifteen-year period at the University Hospitals. Therefore, 17.8 per cent of all brain tumors seen at this institution occurred in children under sixteen years of age. One per cent of all patients admitted to the pediatric service had a verified brain tumor. Of the 146 tumors occurring in children, seventy-nine occurred in males and sixty-seven in females.

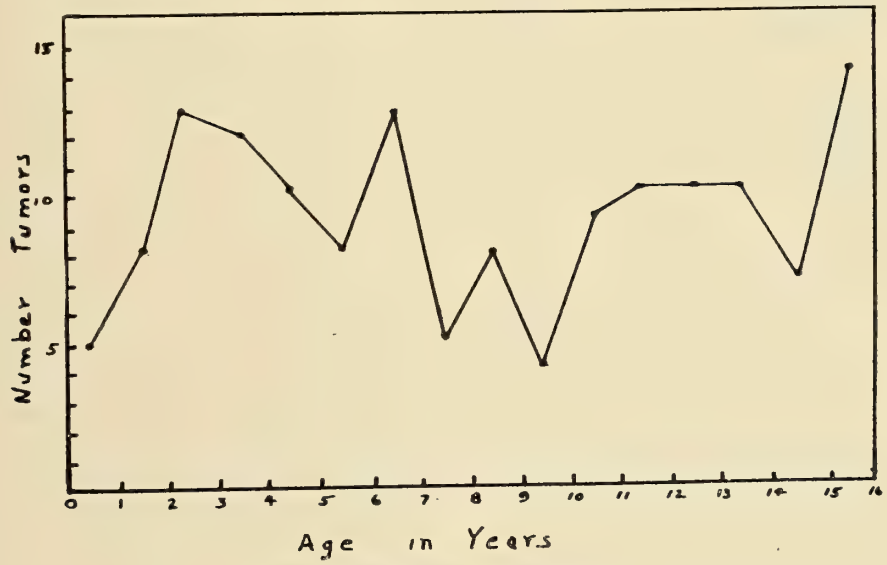

Fig. 1. Age frequency in brain tumors.

There has been considerable discussion concerning the age distribution of the various types of tumors in childhood. Bailey et al[1] and Critchley[3] found the greatest number to occur between the fifth and seventh years of life and attributed this frequency to the preponderence of medulloblastomas in this age group. However, Marburg[11] and Globus[9] found the greatest number to occur before the sixth or after the thirteenth year of life. Figure 1 shows the incidence of tumors in the various age groups in this series. There is a peak incidence at the age of two years which is due to the frequency of ependymomas at this age. It is probable that in a larger series one would

From the Division of Neurosurgery, Department of Surgery, University of Minnesota Hospitals, Minneapolis, Minnesota.

find that brain tumors occur with equal frequency at all ages throughout childhood.

hypophyseal lesions. The more equal distribution of tumors in childhood on each side of the tentorium as found in this series and by other investigators is therefore more representative of the true frequency of their incidence than the ratio in Cushing's material.

TABLE I. LOCATION OF BRAIN TUMORS IN CHILDREN

	Subtentorial			Supratentorial							
	Vermis and Fourth Ventricel	Hemisphere	Pons and Medulla	Pineal	Hypophysis	Third Ventricle	Frontal	Parietal	Occipital	Temporal	Totals

Angioblastoma	2		
Tumors of Mixed Tissue		4	2.8
Cholesteatoma	3		
Teratoma	1		
Tumors of the Hypophyseal Region		4	2.8
Granulomas		6	4.1
Metastatic Tumors		10	6.8
Miscellaneous Type Tumors		4	2.8
Total		146	100.0

Location.—In this series of 146 brain tumors, seventy-one were located above the tentorium and seventy-five below the tentorium. Cushing stated that the relation between supratentorial and infratentorial tumors in children was 2:1. However, there apparently was a selective factor in his material which brought to him a large number of

Table I reveals the location and the histological type of the brain tumors in this series. In the supratentorial region the most frequent site was the third ventricle and areas adjacent to it. The predominant tumor types in this region were astrocytomas, ependymomas, and spongioblastomas. The parietal region was the next most frequent site, and here the ependymomas were the predominant tumor type. In the subtentorial region, midline tumors were most frequent. The medulloblastomas occurred only in this region. In the cerebellar hemispheres the astrocytoma was by far the most frequent tumor. In the pontine region there were predominantly astrocytomas but also a few glioblastomas and other types.

Histological Types.—All the material available for histological examination was reviewed. Special stains were used when needed to verify a specific tumor type. Table II reveals the relative frequency of the various tumor types.

Tumors of Nerves.—There was only one patient with an intracranial neuroma in this series, and she was a fifteen-year-old girl who had bilateral acoustic neuromas that were a part of a generalized neurofibromatosis. During childhood, tumors of the nerves are exceedingly infrequent. When they do occur, they are part of a generalized neurofibromatosis and, therefore, associated with other stigmata of that disease.

Tumors of Meninges.—The origin and cellular characteristics of meningiomas has been the subject of controversy. In this series there were seven children with meningiomas. There were two lipomatous, two psammomatous, one angioblastic, one sarcomatous, and one meningiothelial type. These meningiomas were located supratentorially in five patients and subtentorially in two patients. In three patients there were multiple tumors. The duration of symptoms preoperatively varied from two days in the sarcomatous meningioma to ten years in the case of the lipomatous type.

A definite impression obtained from reviewing these meningiomas in children is that they differ greatly from those of adults with regard to type, duration of symptoms, amenability to surgery, and postoperative course. All terminated fatally within a month, except one who survived four and one-half years, but during that time he had repeated severe generalized convulsions. Whereas meningiomas in adults are one of the more favorable types of brain tumor in regard to prognosis, in children they are apt to be inoperable because of their frequent malignant histological character and the tendency for multiple sites of origin to occur, especially in the case of the lipomatous, angioblastic, and sarcomatous types.

Tumors of Neuroepithelium.—In children, as compared to adults, there is a relative preponderance of glial tissue tumors. This is due to the infrequency, in children, of neuromas and meningial tumors. In this series, 101 (69.1 per cent) of the tumors arose from glial elements.

The astrocytomas comprised the largest subdivision (42 per cent) of the glial tissue tumors. The prognosis in the astrocytoma group was excellent, especially for those located in the cerebellar region. When so located, total surgical excision was accomplished in over 50 per cent of them, and in the remaining a long survival was frequent.

The next largest subdivision (22 per cent) was composed of tumors arising from the ependymal or subependymal tissues. The prognosis in the slow-growing, well-defined papillomas and myxopapillary type of ependymoma was good. However, the rapid-growing, diffuse, cellular ependymomas and ependymoblastomas could seldom, if ever, be totally excised surgically.

The medulloblastomas comprised the third largest subdivision (11 per cent) of the glial tumors. Medulloblastomas arise in the cerebellar vermis and extend into the fourth ventricle. Proper treatment is wide surgical excision of the tumor followed by deep roentgen irradiation. The prognosis for prolonged survival of a patient with a medulloblastoma is poor.

The remaining types of neuroepithelial tumors were seldom encountered. Prognosis in all of them was poor unless they were located in readily accessible regions. The one exception was the pinealomas, for in them good results were obtained with deep roentgen irradiation.

Tumors of Vascular Tissue.—Tumors of vascular tissue are divided into: (1) those comprised of adult vascular elements, and (2) those comprised of embryonic vascular elements (Noran[13]). In the former class are grouped the cerebral telangiectases and the angiomas, whereas in the latter are grouped the angioblastomas.

In this series there were nine children with tumors composed mainly of vascular elements. Seven of the nine were of the parenchymal angiomatous type, and two were of the angioblastic type. The angiomatous lesions were amenable to surgery, except for three located in the hypothalamic region and brain stem. Both angioblastic lesions were in the cerebellum and were amenable to surgery.

Tumors of Mixed Tissue.—Tumors of mixed tissue are now generally accepted as arising from embryonic rests. They are classified into three types, depending upon the number of germ layers present. The epidermoid is composed of elements of but one germ layer, the ectoderm. The dermoid is composed of elements of two germ layers, the ectoderm and mesoderm. The teratoma is composed of elements representing all three germ layers.

In this series there were three patients with epidermoid tumors and one with a teratoma. The epidermoids were located in the suprasellar region and the teratoma in the corpus callosum. Total surgical removal was not accomplished in any of these tumors. When they are located in more accessible regions, a cure can be accomplished by total surgical excision.

Tumors of the Hypophyseal Region.—The two types occurring exclusively in the hypophyseal region are the pituitary adenomas and the craniopharyngiomas. The former are seldom, if ever, symptomatic during childhood; the latter is a frequently seen tumor type. In this series there were three craniopharyngiomas. Removal of all the tumor could not be accomplished in any of them because the lesion in all was adherent to the hypothalamic region.

Granulomas.—The granulomas include the tuberculomas and gummas. In this series there were no gummas, but there were six patients with tuberculomas. The tuberculoma was solitary in only three of these patients. In all six patients there were tuberculomas in the cerebellum and two had additional cerebral tuberculomas. Suboccipital decompression and treatment of the general systemic disease was the therapy of choice.

Metastatic Tumors.—The metastatic intracranial neoplasms are as frequent in children as in adults. In this series there were ten patients (7 per cent) with metastatic tumors. In all of them the metastatic lesion was located supratentorially. Multiple lesions were present in five patients. The primary tumor was carcinoma of the kidney in three, neurocytoma of the adrenal in two, neuroepithelioma of the orbit in two, leukemia in two, and sarcoma of the orbit in one. All the patients expired within five months after onset of symptoms.

Summary.—One in every 100 children admitted to the pediatric service of the University Hospitals has a verified brain tumor.

In children there is an equal frequency between brain tumors located above and below the tentorium.

Brain tumors occur with about equal frequency in each year of the first fifteen years of life.

Tumors of the cranial nerves are infrequent in children. When they do occur, they are apt to be multiple and part of a generalized neurofibromatosis.

Meningiomas in children are usually of a malignant histological character. Compared to meningiomas in adults, the prognosis is poor.

Astrocytomas in children are often localized tumors, of which total surgical excision can frequently be accomplished.

Ependymal tumors vary from the slow-growing papillomas of the choroid plexus with an excellent prognosis to the rapid-growing ependymoblastomas with a very poor prognosis.

Metastatic brain tumors are equally as frequent in children as in adults.

Symptomatology

There are certain fairly constant symptoms that occur in children with brain tumors which lead one to suspect this diagnosis. There are other symptoms which not only indicate the presence of an intracranial tumor but assist in localization. In this report, the frequency and significance of various symptoms and signs caused by such tumors will be summarized.

General Symptomatology.—A change in the patient's personality was the earliest symptom in 20 per cent of the 146 children in this series, and occurred some time during the course of the disease in 40 per cent of them. The frequency of this change was no greater in the children with supratentorial than in those with subtentorial tumors. The children initially would lose interest in playing with other children, then would become so withdrawn that they ceased to play. They would fail to manifest interest in food; they would prefer to "go lie down" than play or eat. Some children became restless, more irritable, and cried or complained readily.

Symptoms caused by a generalized increased intracranial pressure were usually the next indication of the existence of a brain tumor. A headache, usually mild at first and located over the eyes and forehead, occurred in 71 per cent of the patients in this series. Pressure by the tumor on the falx, tentorium cerebelli, meninges or blood vessels, which are innervated by the trigeminal nerve, causes pain to be referred to the region of the cutaneous distribution of this nerve. The headache, which was usually accompanied by vomiting, frequently occurred in the morning after

the child had arisen from bed, and was considered to be due to the change in dynamics of the blood pressure and the cerebrospinal fluid pressure. Following the vomiting, the headache was usually relieved. The headaches were occasionally localized over the occipital and posterior cervical region. Headache so located is due to irritation of the posterior roots of the cervical nerves which supply the dura in the region of the foramen magnum. Tension on the dura in this region causes pain which is referred to the occipital region. Anything that increases the intracranial pressure, such as coughing, sneezing, or straining, may initiate the headaches, vomiting, and occipital pains. Nausea was an unusual complaint. Patients may lose weight because of the anorexia and vomiting. In three of the patients in this series the vomiting was associated with abdominal pain, and this combination of symptoms simulated appendicitis.

Increasing circumference of the head, bulging fontanelles, palpable widening of the sutures, and dilated scalp veins were clear but late indications of increased intracranial pressure. Likewise, a decrease in visual acuity was a late symptom. Decreased vision was due to one of the four following conditions: (1) papilledema, (2) diplopia, (3) primary optic atrophy, or (4) visual field defects.

There was a certain intermittency of all these symptoms especially in the children under eight years of age. This is considered to be due to the intermittent relief of the increased intracranial pressure from the progressive widening of the cranial sutures.

General Signs of Brain Tumors.—Examination of the children with brain tumors in this series revealed, early in the course of the illness, only signs of increased intracranial pressure. The most frequent evidence of such pressure was papilledema. Other evidence of increased pressure was dilation of the veins over the frontal and occipital regions, widening of the cranial sutures, bulging of the fontanelles, and increased head circumference. Extraocular palsies, especially involvement of the sixth cranial nerve, were occasionally present. Roentgenological evidence of increased intracranial pressure was present in 80 per cent of these patients with intracranial tumors.

The presence of congenital deformities such as multiple cutaneous areas of pigmentation, absence of the roof of the orbit, or asymetrical physical development, when present, should cause one to suspect an associated intracranial tumor.

Localizing Symptoms.—Symptoms that are not primarily due to increased intracranial pressure are ataxia, paresis of the extremities, convulsive seizures, polyuria and polydipsia, and abnormal body development.

Ataxia involving primarily the legs or trunk, and manifested by unsteady gait and a positive Rhomberg sign, was present in 60 per cent of the patients with cerebellar lesions. It was much less frequent in patients with tumors in other regions, and for this reason these symptoms are useful in differentiating tumors in these locations.

Paresis of an extremity was found in only 3 per cent of the patients with tumors located in the cerebellum but was present in 40 per cent of those with tumors located in the cerebrum.

Convulsive seizures occured in 16 per cent of the patients in this series. These were either generalized attacks, localized (Jacksonian) seizures, or cerebellar fits. Jacksonian seizures occurred in four patients, and all four had parietal lobe tumors. Generalized convulsive seizures occurred in twenty-five patients; twenty-three of these had cerebral and two had cerebellar tumors. The presence of Jacksonian or generalized convulsive seizures in a patient with a brain tumor was a reasonably accurate indication of a cerebral localization. There were only two patients with cerebellar type seizures, and in both the attacks were very mild. However, these attacks may be severe and accompanied by cyanosis, respiratory irregularities, and unconsciousness.

Polyuria and polydipsia occurred only in patients with tumors so placed that they could exert pressure on, or infiltrate directly into, the hypothalamic nuclei. This occurred in two patients with pineal tumors, four patients with tumors in the hypothalamic region, and one patient with a tumor in the third ventricle. There was evidence of a Froelich-type dystrophy in one patient with a pineal tumor and in two patients with tumors in the region of the third ventricle.

Localizing Signs.—Signs that are of localizing value are cranial nerve palsies, visual field defects, inco-ordination of the extremities, reflex changes,

nystagmus, restricted upward gaze, and stiff neck.

Cranial nerve palsies occurred in 32 per cent of the patients in this series. Cranial nerve palsies can be divided for diagnostic purposes into three groups: (1) involvement of the nerves supplying the extraocular muscles, due to increased intracranial pressure, and hence, without localizing value; (2) involvement of only the eighth cranial nerve, indicating a neuroma of this nerve; (3) involvement of one of the last six (other than the eighth) cranial nerves, suggestive of a tumor located in the brain stem.

Visual field defects were present only in patients who had a lesion along the optic pathway. A field defect associated with a primary optic atrophy indicated a lesion near the optic chiasm. If the field defect was associated with motor dysfunction, the lesion was in either the temporal or temporal-occipital region.

Inability to perform co-ordinated movements of the extremities occurred predominately in cerebellar tumors. There was no difference between the frequency of incoordination in the patients with midline or laterally placed cerebellar lesions.

Reflex abnormalities were more frequently present in supratentorial (64 per cent) than in subtentorial (21 per cent) tumors. When reflex abnormalities were present in patients with supratentorial tumors, the reflexes were hyperactive and the Babinski sign positive. Cerebellar tumors produced hypoactive reflexes, except when there was pressure on, or direct infiltration of, the brain stem by the tumor, in which case the reflexes sometimes were hyperactive. Such involvement of the brain stem was unusual but occurred with sufficient frequency so that the presence of hyperactive reflexes did not positively exclude a subtentorial lesion.

Nystagmus was present in 46 per cent of the patients with cerebellar tumors. It was also frequently observed in patients with brain stem (48 per cent) and pineal tumors (50 per cent), but was very infrequent in cerebral tumors (14 per cent). Nystagmus, when present, can be interpreted as suggestive of a cerebellar, pineal, or brain stem tumor. Cranial nerve palsies occurred frequently with brain stem tumors but seldom with cerebellar tumors.

Restricted upward gaze was present in 80 per cent of the patients with tumors of the pineal gland. It was present only in these patients and was due to involvement of the superior collicular region.

Stiff neck and pain in the posterior cervical region are included with the localizing signs, because in this series they occurred only in patients with cerebellar and pineal tumors. Fifty per cent of the patients with pineal and 36 per cent of the patients with cerebellar tumors had a stiff neck when first seen in this clinic. Both stiff neck and posterior cervical pains are manifestations resulting from reflex spasm of the muscles due to irritation of the cervical nerves by herniation of the cerebellar tonsils and due to irritation of the dura around the foramen magnum, which is supplied by sensory branches from these nerves.

Summary.—The neurological symptoms and signs produced in children by a brain tumor are of two types: (1) nonlocalizing manifestations due to increased intracranial pressure, (2) localizing manifestations due to direct involvement of the brain tissue by the tumor.

Brain tumors in children are not uncommonly associated with congenital developmental defects, such as multiple neurofibromatosis and telangiectases.

Roentgenography

Roentgenography of the skull is a routine procedure in the investigation for an intracranial neoplasm. The value of such an examination is as great in children as in adults. In this report, the abnormalities suggestive of brain tumors, seen in skull roentgenograms of 123 of the children in this series, will be reviewed, and an attempt will be made to show how roentgenography may be of aid in arriving at a correct diagnosis in such patients. Twenty-three of the 146 cases are excluded because of insufficient or inconclusive data.

Roentgenograms taken in the lateral, posterior-anterior, and occipital positions were routine. Stereoscopic views were obtained whenever it was thought that they would provide additional information. Ventriculograms were performed whenever the existence or localization of a brain tumor was in doubt.

Increased Intracranial Pressure.—Three abnormalities frequently observed in patients with increased intracranial pressure are: (1) widening of the cranial sutures, (2) increased convolutional (digital) markings, and (3) erosion of the sella.

Roentgenograms should not be considered indicative of increased intracranial pressure unless at least two of these abnormalities are present. Ninety-nine of the 123 patients had roentgenologic evidence of increased pressure. In children under five years of age, increased pressure was frequently accompanied by widening of the cranial sutures. In children over ten years of age, widening of the more firmly united sutures was less frequent, but erosion of the sella was often seen (Table III).

TABLE III. ROENTGENOGRAPHIC ABNORMALITIES ACCORDING TO AGE OF PATIENT

Age in Years	Number X-rayed	No. With Roentgenographic Evidence of Pressure		Roentgenological Evidence of Pressure					
				Widening of Sutures		Increased Convolution Markings		Erosion of Sella	
		No.	%	No.	%	No.	%	No.	%
0— 5	39	33	85	21	64	18	59	9	27
6—10	37	30	81	18	60	15	50	14	47
11—15	47	36	76	16	44	21	58	19	52
Total	123	99	80	55	55	54	54	42	42

Local erosion of that portion of the calvarium immediately overlying the tumor was also encountered in this series of patients. This abnormality is due to local pressure of the tumor and should not be confused with the erosion of generalized increased convolutional markings which is due to a generalized increase in intracranial pressure. The erosion here referred to appeared discrete and localized. This type of erosion occurred in four patients, and in all of these it occurred at a point overlying the tumor. Thus, such an erosion is an accurate indication of the location of the tumor.

Pineal Shift.—In 1925 Naffziger[12] reported that a shift in the position of the pineal gland may be of great value in localizing brain tumors. However, the pineal gland is seldom calcified until late in childhood and so this method is of less value in children than in older individuals.

Dyke[5] in 1930, Fray[8] in 1938, Dyke and Davidoff[6] in 1940, and Hawes and Mead[10] in 1943 reported that a posterior displacement of the pineal gland may occur in patients with subtentorial tumors. This is just the reverse of the more frequently seen upward shift (Vastine and Kinney[15]) and is believed to be due to an internal hydrocephalus resulting from a small obstructing subtentorial lesion. However, any shift in the pineal gland is unusual in subtentorial tumors, and it was observed in no case in this series.

Intracranial Calcification.—The presence of calcification visible on microscopic examination in a tumor was first described by Rokitansky and Virchow. Since their original description, the presence of calcium in these tumors has become well recognized. In 1925, van Dessel[4] reviewed the incidence of calcification in gliomas and concluded that calcification was the result of degeneration of hyaline in the walls of the vessels. He noted an increased frequency of calcification in tumors of older people as compared with tumors in younger individuals. He also concluded that it could occur in any slow-growing tumor. However, there are several reports in the literature of calcification occurring in very young children and also in rapidly growing tumors (Boldrey and Miller[2]). There was evidence of abnormal intracranial calcification in twenty-five patients in this series, and in every case in which intracerebral calcification was seen it was found to be within the tumor. Thus, the presence of intracerebral calcification in a patient suspected of having a brain tumor is not only excellent evidence that such a lesion is present, but also the calcium indicates accurately the site of the lesion. Table IV reveals the types of tumors in which calcification occurred in amounts sufficient to be visible in roentgenograms. Some assistance in differential diagnosis can also be obtained from the appearance and the location of the calcification. Suprasellar calcification that seemed to outline a cystic cavity was either a craniopharyngioma or a cholesteatoma. Stippled areas of calcification in the occipital or temporal regions were most likely to be oligodendroglioma, ependymoma, or astrocytoma. Calcification that appeared to outline the cerebral convolutions indicated the presence of an angioma.

Skull Metastasis.—Skull defects due to invasion of the skull by metastatic tumors were visualized in two patients. A tumor in young children which is characterized by metastasis primarily to the skull is the Hutchinson-type neuroblastoma of the adrenal gland. The skull metastasis in this series were from that type of tumor (Table IV).

TABLE IV. LOCALIZING ROENTGENOLOGICAL EVIDENCE OF BRAIN TUMORS IN CHILDREN

Type of Tumor	Calcification	Local Erosion	Metastasis
	No.	No.	No.
Meningioma	2	1	
Astrocytoma	5	2	
Angioma	2	1	
Ependymoma	5		
Cholesteatoma	3		
Craniopharyngioma	3		
Spongioblastoma	1		
Pinealoma	1		
Oligodendroglioma	1		
Astroblastoma	1		
Tuberculoma	1		
Adrenal neuroblastoma			2
Total	25 20.3%	4 3.2%	2 1.6%

Ventriculography.—Ventriculograms were performed in thirty-eight of the 123 patients and were of value in localizing the lesion in twenty-nine of them. In seven patients the ventriculogram was of no diagnostic value. In four of these seven patients, insufficient air was injected, and in the other three there was no abnormality recognized in the ventriculogram even though the ventricular system was well visualized. Poppen and Peacher[14] recently have reported ten cases of verified supratentorial tumors with normal air studies.

Ventriculography was not only of value in determining the presence and localization of the lesion but also was of assistance in judging the operability of the tumor. In this series it was decided that the lesion was inoperable, because of the roentgenographic appearances, in only one patient. This was an extremely diffuse astrocytoma located around the third ventricle. In four patients there was an upward displacement of the posterior horn of the lateral ventricle on one side. This is an unusual defect and was correctly interpreted in all four as significant of a posterior fossa lesion.

Encephalography.—It is inadvisable to perform an encephalogram on a patient with a brain tumor, but sometimes a brain tumor is present but not suspected prior to performing an encephalogram. This is especially true in children because of the frequency of vague neurological signs and symptoms.

In this series, encephalograms were made on eleven of the 123 children. In six of the eleven patients the tumor was demonstrated to be present. In the remaining five patients the air studies were noncontributory. They were noncontributory in two because insufficient air entered the ventricles to outline them well, and in three there was no air in the ventricular system whatsoever.

Summary.—Roentgenograms of the skull revealed evidence of increased intracranial pressure in 80 per cent of children with brain tumors.

Abnormal intracranial calcification was visible in roentgenograms in 20 per cent of children with brain tumors and was an accurate indication of the localization of the tumor.

Ventriculograms were of localizing value in 78 per cent of the children with brain tumors in whom such studies were performed.

AUTOMATIC ATTENTIVE BREATHING IN ANGINA PECTORIS

AARON FRIEDELL, M.D.
Minneapolis, Minnesota

IT WAS in August of 1924 that P. C., aged fifty-four, emphasized the relief he had obtained one day from a severe attack of angina pectoris, when his attention was suddenly diverted to a bird singing on a treetop nearby. At that time this patient had had frequent attacks of chest tightness and chest pain for eight months. He volunteered information further that after that experience he found he could abort an attack at will or shorten one by actively pretending that he was "listening to a bird sing on a treetop," providing he promptly stopped whatever he happened to be doing at the moment and turned his attention to his breathing, while he endeavored to keep himself fully at ease and relaxed. As he demonstrated it to me, his technique consisted in a slowed-up and protracted inhalation, with his chest expanding very slowly during inhalation. His exhalation was slow also, and there was a definite pause between each phase of his respiration. He paid special attention, he informed me, to maintain the chest muscles and his arms relaxed.

I have since modified that technique. I teach diaphragmatic breathing with attention to both phases of respiration and the intervening pauses. In addition, I have added at least one breathing exercise that I prefer to call obstacle breathing. It is done by alternately closing one nostril while inhaling slowly through the other. In so doing, one seems to improve the diaphragmatic type of breathing.

I encouraged this patient to continue this practice because he thought it helped him, but I did not comprehend the significance of it for several years, even though in December, 1927, P. Yogananda[27] called my attention to the values of attentive breathing. Later, circumstances, a search through the literature on respiration and a careful analysis of the physiological factors involved in the act of "listening to a bird," as demonstrated to me by P. C. on several occasions, finally convinced me that "attentive respiration" may be a valuable exercise in some heart ailments, and should be investigated for its potentialities. Hence, I am reporting on eleven cases carefully observed for long periods, in which I considered that breathing exercises were of definite value although I did not consider my controls fully adequate. It was not possible to make my patients quit the respiratory exercises that they learned and which they felt gave them relief in times of distress. After they mastered attentive breathing, it gradually became automatic with them, and they would automatically turn to those exercises at the first approach of any sign of distress. My only control was to keep each patient under observation for at least four weeks or more, on medication, rest and sedatives, before teaching the automatic attentive breathing exercises. However, I am offering this for what it may be worth, and so that others may try it.

Case Reports

Case 1.—P. C., mentioned above, was fifty-three years of age when he had an attack of coronary thrombosis in the fall of 1923 and was confined to his home for over one month. He came to my office the first time in July, 1924, with the chief complaint of frequent attacks of sudden severe pain in his heart area radiating to his left arm. All of his physical findings, as well as blood studies, blood Wassermann test and urinalysis, were negative. The electrocardiographic findings were indicative of myocardial damage on the basis of coronary disease. A diagnosis of coronary disease with angina pectoris was established, which was later confirmed at the Mayo clinic. The patient was a railroad passenger locomotive engineer. He was given the usual medical care, including 1/100 gr. nitroglycerine tablets for sublingual use which he required to obtain relief from symptoms about three or four times a day. However, a few weeks after his accidental discovery of "listening to a bird," and subsequent repeated use of this respiratory technique, he no longer required any drug therapy.

The railroad company did not allow him to work on a passenger locomotive after his first attack, because of the possible risk to lives of passengers, but he worked on freight engines in the roundhouse until his retirement, because of his age, when he became seventy years old. Thus he worked at a harder job for those sixteen years following the initial attack. He died on October 6, 1947, from a cerebral hemorrhage at the age of seventy-seven years. He was in good condition as far as his cardiac ailment was concerned up to the date of his sudden death.

Case 2.—H. R., at the age of thirty-one, had noticed chest pressure and pain after exertion. This became progressively worse and often radiated to either arm

or both arms. His attending physician found hypertension and left heart enlargement. He recommended a vacation, sedatives and nitroglycerine, and later a reduced work schedule.

one year later. He had been taking sedatives regularly and nitroglycerine sublingually, two to four times nearly every day, for about two years before calling on me. Any exertion or a rapid stride in his walking would

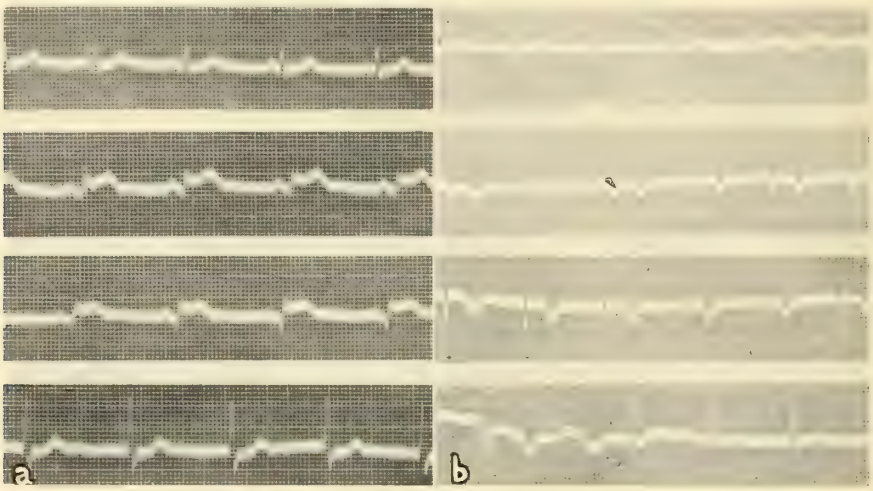

Fig. 1a (Case 4). Electrocardiogram taken at onset, showing a split QRS complex in lead II, a deep Q wave in lead III, an elevated ST interval in leads II and III, and a depressed ST intervals in lead IV.

Fig. 1b (Case 4). Electrocardiogram taken two months later showing different abnormal tracing.

This patient came to me in September, 1926, one year after his first attack but still having symptoms. His physical examination was essentially negative except for a rigid and malformed right elbow which he had fractured at the age of eleven. His blood studies, the blood Wassermann test and urinalysis were all negative. His 6-foot chest plate showed a left-sided hypertrophy of the hypertensive type. His blood pressure varied between 190 and 174 millimeters of mercury systolic, and the diastolic remained constantly at 108 millimeters of mercury. His pulse varied between 76 and 84 per minute. His basal metabolic rate was + 3.

One day, this patient called soon after P. C. (reported above) had left my office. Because of the recent experience with P. C., it occured to me that I might try to teach H. R. attentive respiration exercises. Of course, I did not discontinue any of his medications. He always carried nitroglycerine tablets for sublingual use, and he had used them occasionally. He noted gradual improvement of symptoms over the next twelve months' period, and during the following year he discontinued all drug therapy. He has been free from chest pains now for over eighteen years. I see him frequently, and I consider him as being fully relieved of his symptoms. He is carrying on his vocation with full responsibilities. He still has his hypertension, usually 170/100. His electrocardiogram has always been normal, and it is normal now.

Case 3.—G. T., a retired minister, aged sixty-seven, came to me in October, 1937. He gave a history of having had an acute attack of coronary thrombosis three years previously and another attack of lesser severity bring on chest tightness and pain. A diagnosis of angina pectoris and coronary disease was made. After he was under my care for ten weeks, he too was taught breathing exercises. He continued with other medications as before. He called on me about once a week at first and later less often. It is now nearly ten years since he has taken any medication at all, and he states that he has "forgotten whether he has a heart or not." The improvement in this case also came on gradually, so that I was not aroused enough to attribute seriously the improvement in his cardiac trouble to respiratory exercises. However, later cases observed more carefully and a search through the literature have caused me to think that there could be respiratory techniques or exercises for easing cardiac distress.

Case 4.—On August 1, 1943, A. F., aged fifty-three, became suddenly very ill. He was apparently well up to the moment of his sudden attack. While he was listening to the radio newscast at 8:00 a.m. that the American troops were landing on one of the Aleutian Islands, he suddenly became aware of severe pain at the left of the upper end of his sternum. This became progressively worse. Within a few minutes he was covered with profuse perspiration and became ashen grey in color. He was given a hypodermic injection of ¼ grain of morphine which only relieved him partially. He was put to bed promptly. At 10:00 a.m. he took ¼ grain of morphine by mouth, and at 1:00 p.m. he was given papaverin hydrochloride, 3 grains intravenously. He ran an elevated temperature of about 101.4° for five days. His sedimentation rate was 26 mm. in sixty minutes. His leukocyte count was 14,000. His electrocardiogram showed myocardial damage (Fig. 1).

He was confined to bed for over six weeks. The consultant cardiologist at first thought that his prognosis was rather poor. The diagnosis was coronary thrombosis with myocardial damage.

quality, and no thrill, murmur or friction rub was elicited. The blood pressure was 136/82.

On the mere suspicion of a possible heart involvement, this patient was kept in bed for a few days. On

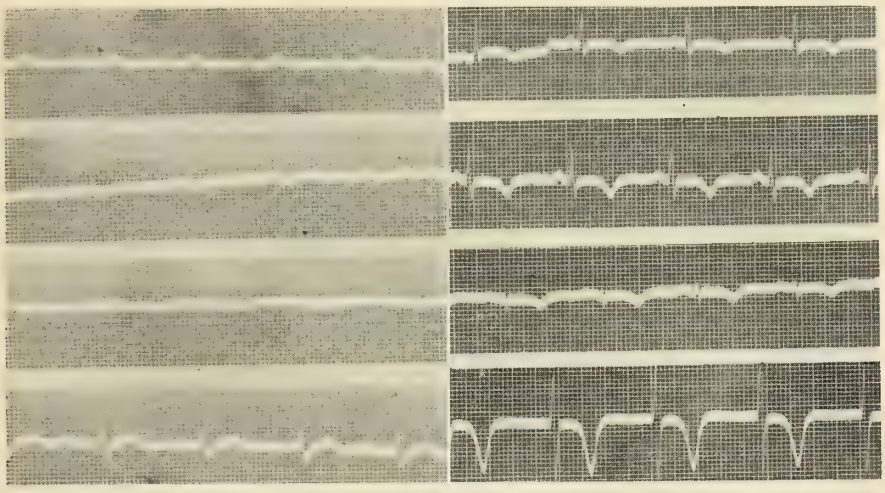

Fig. 2 (Case 5). Electrocardiogram taken in June, 1946, interpreted as within normal limits except for showing a low potential in all leads.

Fig. 3 (Case 5). Electrocardiogram taken six months later showing negative T waves in all leads, not present in Figure 2 and indicating considerable myocardial damage.

This patient was given morphine when he needed it the first five days. He took aminophylline, 3 grains three times a day, for about a month. This patient could not turn on his left side for a long time after his acute attack. He claimed that he became aware of palpitation and the heart would skip a beat now and then if he turned on his left side. He was left rather weakened, and could not do much at first in the early weeks of his recovery without bringing on some tightness and pain in his chest. He could not walk his usual gait without causing chest tightness and pain. He was taught attentive breathing exercises on the tenth week of his ailment. He volunteered the information shortly afterwards that turning his attention to "proper breathing" soon removed his chest pain. To date, this patient is back to his full duties, although he restricts his activities somewhat as a precautionary measure. He attributes his well being to the practice of "attentive breathing" a few short moments several times each day.

Case 5.—R. K., a housewife, aged thirty-eight, had her first attack of chest tightness and pain on June 8, 1946, when she suddenly felt severe pains in her left upper chest, which lasted over a half hour. By the time I saw her at her home, the pains had eased considerably and she felt rather tired out. A physical examination at the bedside did not reveal anything unusual. Her temperature, pulse and respiration were normal. The pulse rate was 80 and of good quality. The physical examination was essentially negative. The lung examination revealed normal breath sounds throughout the chest. No areas of dullness and no râles were found. The heart tones were of good

June 28, 1946, she came into the office. Her physical findings were the same except that the blood pressure was 150/100, the hemoglobin was 75 per cent, the red blood cell count was 3,750,000, the leukocyte count was 11,200 and the sedimentation rate was 20 mm. in sixty minutes. The electrocardiogram (Fig. 2) revealed a low potential in all leads but otherwise was interpreted as within normal limits. On November 12, 1945, she came in complaining of pain in the stomach that came on at irregular intervals, and she stated that often if the pain lasted a while, it would then radiate to her chest, producing a tightness around the heart and some difficulty in breathing. X-ray studies of the gastrointestinal tract, including a barium enema of the colon, proved to be negative. A 6-foot chest plate revealed normal heart and lung shadows. The blood examination revealed a sedimentation rate of 35 mm. in sixty minutes. Her hemoglobin was 82 per cent, red blood cell count was 4,100,000 and leukocyte count was 9,550.

This patient went to Florida in December, and on her return trip she had another attack of severe chest pain in a hotel lobby, for which she was given a hypodermic injection by a physician.

On January 8, 1947, she came in complaining of frequent feelings of chest tightness, some pain and dyspnea on exertion. The electrocardiogram now (Fig. 3) showed a negative T wave in all leads, evidently indicative of considerable myocardial damage. This patient was kept at bed rest for two weeks, and after that she was allowed to be up but her home duties were restricted considerably.

Her past history may have been contributory to her recent ailment. She had had considerable upper respiratory difficulty. She had had three miscarriages, two

of them self-induced. In October, 1935, she went into labor at term and developed eclampsia. Her blood pressure went up to 200/120 from 126/84 within two hours. She had several convulsions and remained unconscious for twelve hours until she was delivered of a stillborn fetus whose cord was tightly wound four times around its neck. She made an uneventful recovery, and her blood pressure returned to her previous normal. However, her previous occasional headaches became much worse after this pregnancy. She was actually confined to bed for two or three days every month during her menstrual period due to "migraine" headaches. On July 24, 1937, she delivered a normal baby girl following a normal pregnancy and delivery. A few months after this delivery she again resumed having her headaches at irregular intervals. In June, 1939, she had a cholecystectomy and a left-side oöphorectomy.

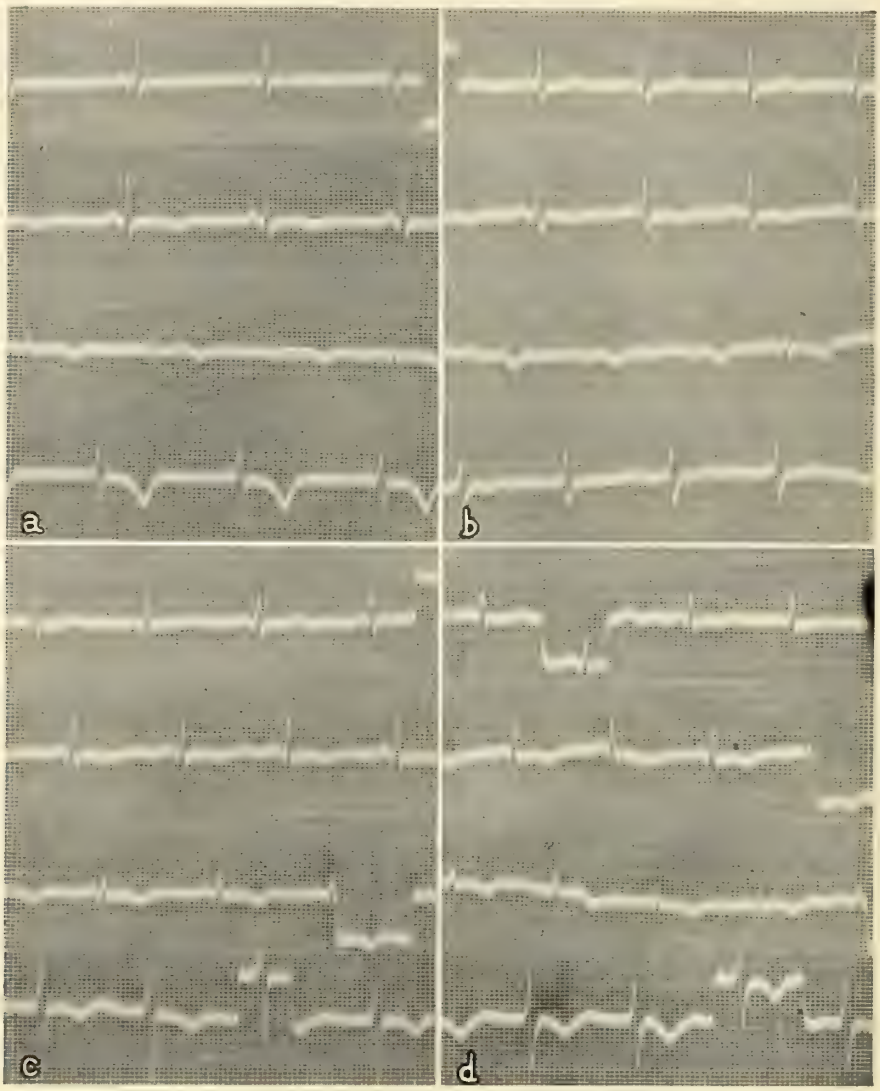

Fig. 4 (Case 5). Electrocardiograms taken (a) March 8, (b) March 13, (c) March 24, and (d) April 7, 1947, showing progression of myocardial disease.

On March 7, 1947, at about 8:00 p.m. following moderate exertion she suffered a very severe heart attack. The chest pain and tightness was very severe. Her dypsnea was very marked. She complained constantly that there was no air in the room. She was given an injection of ¼ grain of morphine and was hospitalized promptly and placed in an oxygen tent. A diagnosis was made of coronary thrombosis. Her progress in the hospital was rather poor at first. She had four acute attacks during her hospital stay. Her electrocardiogram on March 8, 13, 24 and April 7 all showed evidence of myocardial damage indicating progression of coronary disease (Fig. 4, a, b, c, d). Her sedimentation rate was 35 mm. in sixty minutes. The leukocyte count was 11,000. The patient was given dicumarol and other usual medications. She had a difficult time for over four weeks. Later, she too was taught to practice attentive breathing several times a

day. From observing her carefully, I believe it has contributed to the relief of her symptoms.

Six more cases of angina pectoris which were relieved of their symptoms by attentive respiration were briefly as follows:

Case 6.—H.R.S., male, aged fifty-nine. The established diagnosis after a careful examination was angina pectoris and mild diabetes. Length of observation was six years; and practicing attentive respiration for two years afforded him relief from symptoms.

Case 7.—E. F. S., male, aged fifty-six. The diagnosis was (1) angina pectoris following an attack of acute coronary thrombosis on July 16, 1943; (2) diabetes, diagnosed in 1939, requiring a daily dose of 45 units of insulin; and (3) hypertension with a blood pressure variation of 190 to 170 millimeters of mercury systolic and 110 to 100 millimeters diastolic. This patient had considerable anginal symptoms following his acute coronary episode. He was started on exercises of attentive respiration four months after his attack and he gradually obtained relief from his symptoms. He died September 5, 1947, following a cerebral hemorrhage and pulmonary thrombosis; however, in the interim he had obtained relief from anginal symptoms apparently through practicing attentive respiration and frequent short rest periods.

Case 8.—Mrs. B. R., female, aged forty-seven. Diagnosis was angina pectoris. The length of observation was three years. She has been practicing attentive respiration with absence of anginal symptoms for two years.

Case 9.—Mrs. M. S., female, aged fifty-two. The diagnosis was angina pectoris for the duration of two years. She obtained relief from her symptoms practicing attentive respiration for one year.

Case 10.—Mrs. M. O'B., female, aged seventy-one. The diagnosis was hypertension and angina pectoris. Her blood pressure was usually about 220 millimeters of mercury systolic and 120 diastolic. She obtained relief from symptoms by means of attentive respiration over a period of one year.

Case 11.—Mrs. M. F., female, aged sixty-five. She had suffered from hypertension for over ten years and was under my care for one year. The blood pressure reading varied between 260/130 and 210/124 millimeters of mercury. She had marked heart enlargement and anginal symptoms. She obtained relief from anginal symptoms by practicing attentive respiration exercises during a period of one year.

Discussion

The rationale for the help obtained from attentive breathing may well be attributed to the following considerations:

1. Potts,[23] Blair, Bell,[3] Falk[7] and others have called attention to therapeutic values obtained from breathing exercises in coronary thrombosis and pulmonary embolism.

2. According to Negovski,[19] the heart is one of two body organs that has "greatest recuperative power of all body organs." Attentive respiration probably affords favorable conditions for the recuperating heart, as I shall try to show later.

3. Macklin[17] has shown that during inhalation the blood vessels in the lungs not only lengthen but they also widen in caliber, thus increasing the blood vessel volume in the lungs, so that the blood is better areated. Undoubtedly it is for that reason that the editorial writer of the American Medical Association[6] calls the lungs "the secondary heart." Hence, increased inhalation time obtained in attentive breathing may be of value for a recuperating heart.

4. As one of the factors contributing to the possible values in attentive respiration, I wonder if the lungs may not have a massaging action upon the myocardium during inhalation when the lungs expand with air. Haldane,[12] in his book *Respiration,* states: "We bethought ourselves of some anatomical observations collected by Professor Arthur Keith in *Further Advanced in Physiology,* edited by Professor Leonard Hill, 1909. He showed in this essay that during inspiration the lungs do not expand equally and simultaneously at all parts, but open out part by part somewhat like the opening of a lady's fan. The parts nearest the moving chest walls (for distance, the diaphragm) expand first, and other parts follow." In diaphragmatic breathing we may well have expansion of the lungs from below upward toward the apices of the lungs, and in such lung distention there may be a massaging action upon the heart from its apex toward the base of the heart or a massaging action along the course of the coronary veins. When I watched patients in attentive breathing during relaxation, it seemed to me that they were doing diaphragmatic breathing, which may be of benefit by this apparent massaging action.

5. The lengthened time element and the reduced respiratory rate may be valuable factors to be considered in the help obtained from attentive breathing. Normal respiratory rates are usually considered to vary from about sixteen to twenty per minute. During inspiration the lung

tissues stretch and the stretching stimulates the vagus nerve.[2] However, H. R. (Case 2) has so well mastered his respiration while at rest that he breathes about three times per minute (Fig. 5) and very often I have observed him breathing only two times per minute, which means that the average duration of each respiratory phase was 10 to 15 seconds. All this brings to mind statements of August Krogh[14] as a result of his own work and that of others, that there is a latent period of between 4.6 and 8 seconds for the reaction of the autonomic nervous system, while A. J. Clark[4] claims the latent period to be 15 seconds. At any rate when the respiratory rate is not interfered with by the voluntary nervous system and is only two per minute, which means 15 seconds per respiratory phase, it is possible that more nerve endings will respond to the stretch stimulus than when the respiratory rate is 20 per minute, which means 1⅓ seconds per respiratory phase. When the nerve endings of the parasympathetic are stimulated,[2,4,10,11,16] acetylcholine is produced, which according to August Krogh[14] and A. J. Clark[4] constitutes a relaxant to the muscular layers of the blood vessels of the cholinergic system. But the acetylcholine thus produced at the nerve endings has but a brief moment for effective work, for acetylcholine is quickly destroyed by cholinesterase[11] that is present everywhere in the tissue. Hence, the longer inhalation period probably affords more acetylcholine production and smooth muscle relaxation. Also the increased acidity of inhalation following a lengthened exhalation counteracts the cholinesterase function[10,14] as will be shown later.

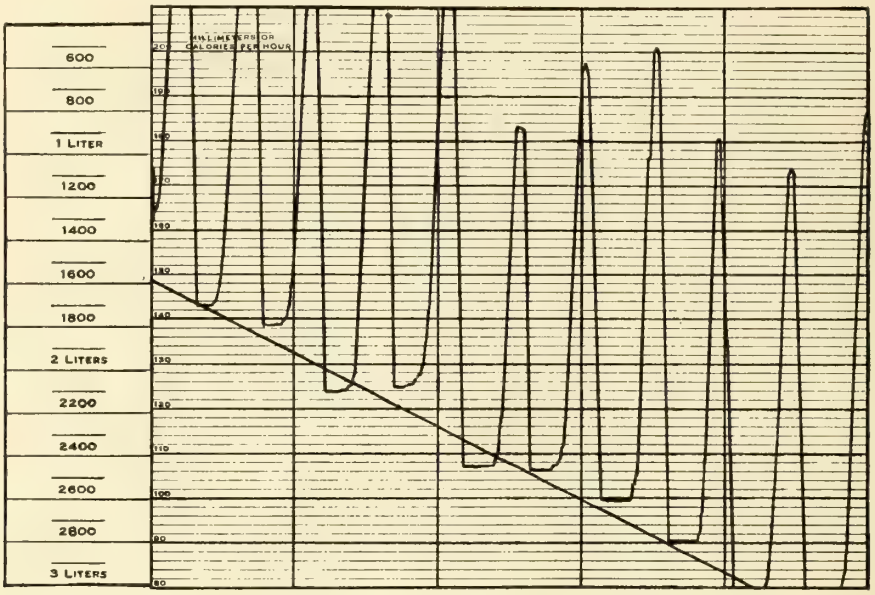

Fig. 5 (Case 2). Respiration chart illustrating an automatic respiratory rate of less than 3 per minute.

According to VanSlyke and others,[26] respiraton has a definite influence on the acid-alkaline balance of the living organism. The hydrogen ion concentration of the blood averages pH 7.4, but it fluctuates with respiration. During inhalation it becomes more acid, and the pH may go to 7.1, and during exhalation, when carbon dioxide is blown off, the blood becomes more alkaline, and it may reach a maximum of pH 7.8. The fluctuations in the acid-alkaline balance are less with shallower breathing. Otto Loewi,[16] Gesell, Brassfield and Hamilton,[9] Stella,[25] Clark[4] and others have shown that acetylcholine production is more favored by an increased amount of carbon dioxide in the inspired air. Now, when the respiratory rate is slower and deeper, the expired air will naturally have a greater percentage of carbon dioxide at the end of expiration.[22] So that on the following inhalation more carbon dioxide will be returned from the residual air space, thus favoring acetylcholine production. Gesell and Hansen[11] state, "An acid-moderating mechanism is built into the very foundation of nervous integration." Nechels and Gerard[18] state, "Exposing a stretch of nerve to carbon dioxide causes a marked

increase of total action potential up to five times the initial values." From the work of Gesell and Hansen,[11] and Nechels and Gerard,[18] it could be surmised that on inspiration, after a slow and lengthened expiration, the vagal nerve endings are being stretched and stimulated more in the presence of a greater amount of carbon dioxide than in shallow breathing, which in turn means a greater production of acetylcholine and a greater inhibiting action upon cholinesterase by increased acidity.

6. The improvement in the arterial oxygen saturation that comes from slow deep breathing is undoubtedly another favorable factor in attentive breathing. Comroe and Dripps[5] show that during inhalation the average alveolar oxygen pressure is 105 millimeters of mercury while during exhalation the average alveolar oxygen tension is 95 millimeters of mercury. A lengthened time interval for the higher alveolar oxygen tension is undoubtedly of value in supplying oxygen.

Best and Taylor[2] discussing shallow breathing and deep breathing indicate that arterial oxygen saturation is favored by slow deep breathing, rather than shallow rapid breathing, despite the fact that the minute volume of air breathed by shallow rapid breathing is greater than the minute volume of slow deep breathing.

Barach, Fenn, Ferris and Schmidt[1] in their work on "The Physiology of Pressure Breathing" show among other things that "a lowering of carbon dioxide pressure is advantageous because it permits the arterial blood to take up more oxygen in the lungs at the same oxygen pressure." It is evident that both intravenous and alveolar carbon dioxide pressure continue to fall during exhalation. For, as Best and Taylor[2] indicate, carbon dioxide is eliminated very quickly since the tissue permeability for carbon dioxide is thirty times that of oxygen; and of course a lowering of carbon dioxide alveolar pressure is obtained when exhalation is more complete and lengthened, while muscle tensions are consciously relaxed. All this seems to indicate that automatic slow respiration, both in the inhalation and exhalation phases, may reasonably be of value in the relief of symptoms in angina pectoris.

Conclusion

Attentive respiration was utilized as an adjunct in the treatment of eleven cases of angina pectoris, apparently contributing in their relief of symptoms.

I wish to express my thanks to Dr. George Fahr for his criticism.

EARLY AMBULATION: CLINICAL RESULTS AND PREREQUISITES

KARL A. MEYER, M.D., DONALD D. KOZOLL, M.D., and NICHOLAS CAPOS, M.D.
Chicago, Illinois

SINCE 1944 we have adopted the plan of early postoperative rising for our surgical patients. This practice is now so widely used that a review of the literature leading to this decision would be repetitious, particularly with the recent appearance of a monograph by D. J. Leithauser,[11] who is generally credited with repopularizing the procedure in this country. In fact, his bibliography lists 126 references for the history of early ambulation up to 1945; interest in this subject has resulted in additional papers since 1945.

The purpose of this presentation is to give our clinical results with this technique, to compare these results with a control series, and to discuss the principles of preoperative and postoperative care, which we feel must be mastered before properly applying this method.

Between the years of 1944 and 1947, 250 consecutive patients were selected who had been operated on for one of five different standard surgical procedures: gastric resection, colon resection cholecystectomy, hysterectomy, and herniorrhaphy. These procedures were selected because they represented varying degrees of surgical trauma. For purposes of comparison an equally distributed consecutive series of patients operated upon between 1939 and 1943 were studied as an example of late ambulation.

Clinical Results

Figures 1 to 5 illustrate the day of ambulation and the type of complication occurring with the entire group of 500 patients. The results will be compared first for each type of surgical procedure and then for the group as a whole.

Gastric Resection.—(Fig. 1) Fourteen complications occurred in fifty gastrectomies performed during the era of delayed ambulation. Four of these resulted in death. Of the nonfatal complications, thrombophlebitis and bronchopneumonia (probably atelectatic) were the most common. There were five complications in fifty gastric resections performed during the period of early postoperative rising without any deaths. Pulmonary complications were the most frequent ones seen.

Colon Resection.—(Fig. 2) In fifty patients of this group kept in bed for varying periods postoperatively, there were sixteen complications with seven deaths. Death was due most often to postoperative pneumonia. Another frequent complication in this period was wound infection. Of fifty patients resected during the recent period of earlier ambulation, there were twelve complications with one death. Pneumonia was a frequent postoperative complication but it was less often fatal. For unexplainable reasons, cystitis was seen more frequently in the latter period.

Cholecystectomy.—(Fig. 3) There were fourteen complications in fifty cholecystectomized patients allowed to remain in bed postoperatively; one of these resulted in a fatality. Abdominal distention was noted frequently as a postoperative complication. Of the parallel group of patients ambulated early after cholecystectomy, the only complication noted was a nonfatal postoperative pneumonia in one patient.

Hysterectomy.—(Fig. 4) In the group allowed prolonged bed rest after hysterectomy, there were five complications whereas in the group encouraged to ambulate early there were none. There were not enough complications of any one type to indicate a trend. There were no deaths in either group.

Herniorrhaphy.—(Fig. 5) The majority of these were of the inguinal type in which operation was performed under spinal anesthesia. There were six complications in the fifty patients treated by late rising and four complications in the fifty patients obliged to rise early. There were no deaths in either group.

Influence on Postoperative Temperature and Hospitalization.—A shorter and lessened febrile period has been described for the patient who

From the Departments of Surgery of the Cook County Hospital and Northwestern University School, and the Cook County Graduate School of Medicine, Chicago, Illinois.

Presented before the Saint Paul Surgical Society, April 26, 1947, Saint Paul, Minnesota.

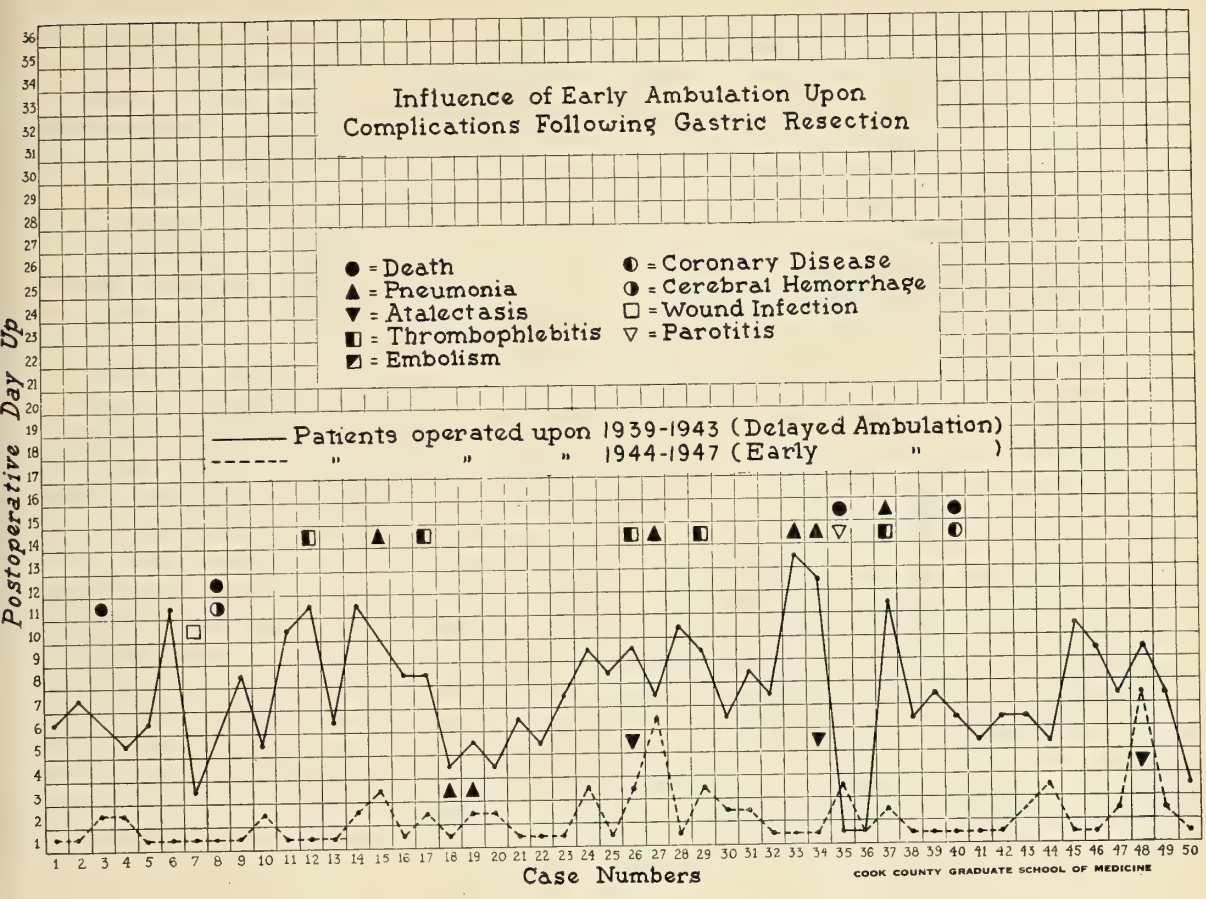

Fig. 1.

has ambulated early.[18] Our own series indicates a decrease in the average maximal postoperative temperature from 0.4° to 1.2° F. (Table I).

A shortened period of hospitalization would be anticipated as a result of early ambulation. Considering the individual surgical procedure it was found that following gastric resection, the early ambulated patient left the hospital on an average of 2 days earlier. 3.1 days earlier after colon resection, 5 days earlier after cholecystectomy, 2.7 days earlier after hysterectomy, and 2.4 days earlier after herniorrhaphy. In each instance all sutures were removed before discharge, and no patient was permitted to go home in the presence of a complication.

TABLE I. INFLUENCE OF EARLY AMBULATION UPON POSTOPERATIVE TEMPERATURES AND PERIOD OF HOSPITALIZATION

Operation	Number of Patients	Average Maximum Postoperative Temperature	Average Postoperative Hospital Discharge Day
Cholecystectomy			
Group I	50	102.2	14
Group II	50	101	9
Colon Resection			
Group I	50	102.2	24.7
Group II	50	101.8	21.6
Gastric Resection			
Group I	50	102.6	14
Group II	50	102	12
Hysterectomy			
Group I	50	101.4	12.6
Group II	50	100.8	9.9
Herniorrhaphy			
Group I	50	100.6	11.1
Group II	50	100	8.7

Group I: Operated upon 1939-1943—Delayed ambulation.
Group II: Operated upon 1944-1947— Early ambulation.

Total Complications.—In Table II total complications are aggregated for the 500 patients. A total of ninety-eight complications in 500 operations was experienced, of which twenty-eight occurred in the group ambulated early and seventy in the group ambulated late. This means that 11.2 per cent of the patients treated by early ambulation experienced complications whereas 28 per cent of those treated with late rising had such complications.

Considering the individual complication, it was found that out of thirteen deaths in the group of 500 operations, all but one occurred in patients

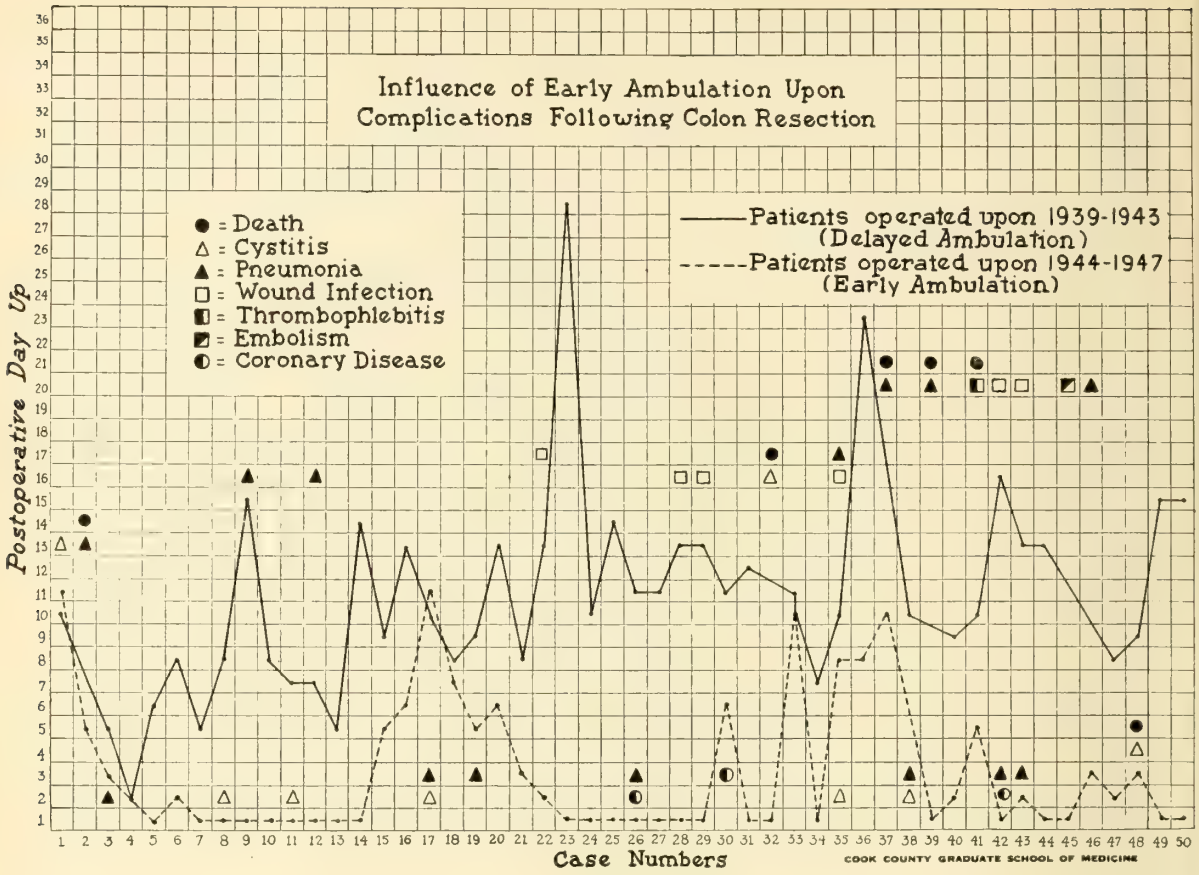

Fig. 2.

TABLE II. INCIDENCE OF COMPLICATIONS IN 250 PATIENTS TREATED BY EARLY AND LATE AMBULATION AFTER OPERATION

	Early Ambulation	Late Ambulation
Deaths	1	12
Pneumonia	10	16
Atelectases	3	3
Abscesses	0	2
Wound Infections	0	8
Thrombophlebitis	0	7
Cystitis	6	5
Pulmonary Embolism	0	1
Abdominal Distention	1	9
Bronchitis	3	1
Miscellaneous	4	6
Total Number of Complications	28	70
Percentage	11.2%	28.0%

who were detained in bed after the operation. Pneumonia occurred not only more often in the late risers but it was more often fatal. Postoperative infections, thrombophlebitis, and distention were seem more frequently in the group remaining in bed after operation. No significant difference in the incidence of atelectasis or cystitis could be discerned.

In the evaluation of these differences one might question whether or not changes in postoperative care might be a factor. While it is true that antibiotic therapy was introduced during the latter period of early ambulation, sulfonamides were available to the previous group, and blood transfusions and intestinal siphonage was available to both. Although it can be reasonably assumed that this change in chemotherapy may have well resulted in a lowered incidence of fatal pneumonia and serious postoperative infections, it would not adequately explain all the differences seen.

Surgical Prerequisites for Early Ambulation

As every paper on early ambulation hurriedly confesses, early ambulation is *not* a new procedure, and Emil Riese of Chicago is given credit for first reporting this procedure in 1899.[17] However, with few exceptions, the entire plan soon fell into disrepute in this country, but it continued to be practiced widely on the continent. The present revival has met with significant success,

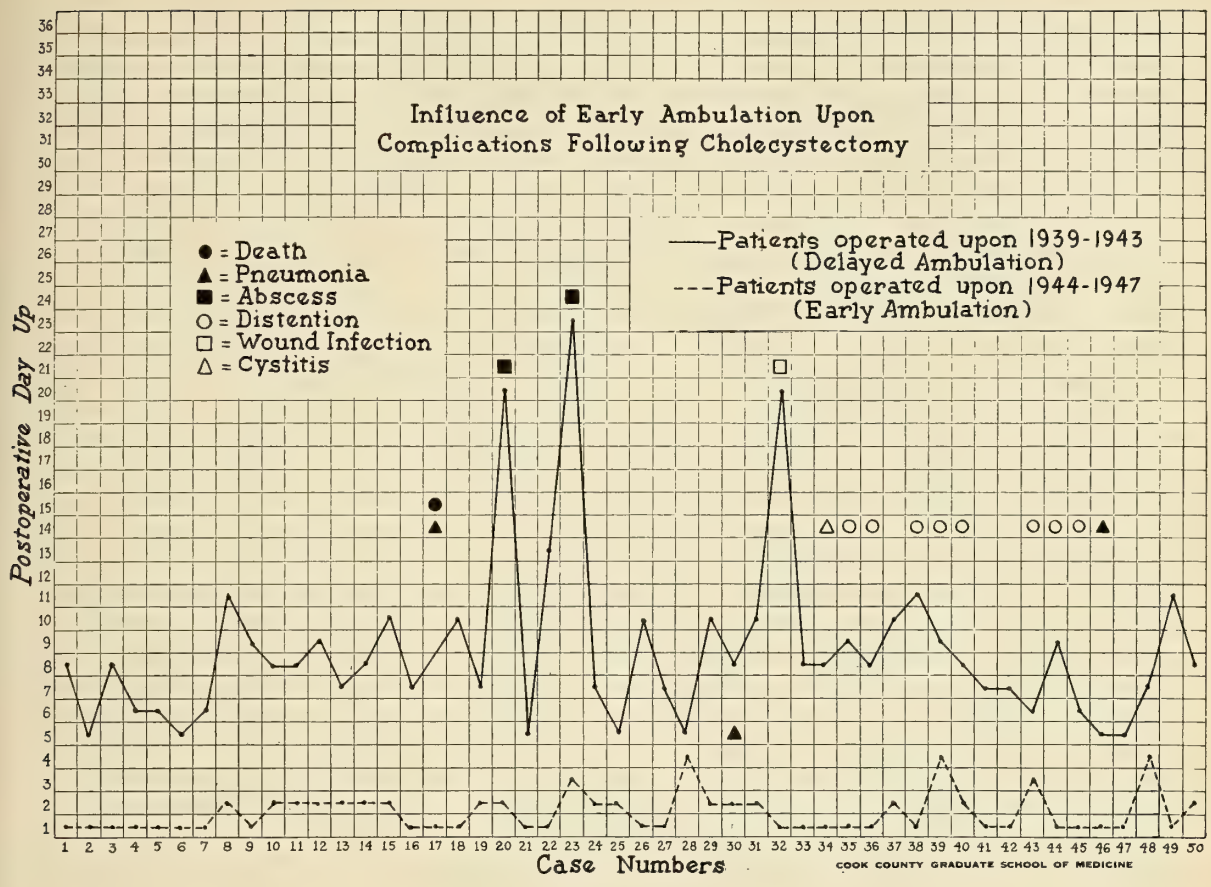

Fig. 3.

and if it continues to be so we believe it will be because of the application of sound physiological principles in preoperative and postoperative care. We consider the following ten principles as requirements to be fulfilled in the main before embarking upon this plan.

1. *Correction of dehydration* is paramount. Dehydration exists in a variety of surgical diseases, particularly in the presence of obstructing lesions of the gastrointestinal tract, diarrhea, fistulas, peritonities, burns and draining wounds.

In the presence of dehydration, there is a marked reduction in the plasma volume which leads to the development of shock. This reduction in the plasma volume also entails reduction in urinary excretion, with a consequent retention of nitrogen waste products. A decreased plasma volume affects the function of such important viscera as the liver, brain and the heart, any of which will render the patient a poor surgical risk.

The correction of dehydration implies the administration of water containing salt, carbohydrates and protein. This can be accomplished most rapidly by the intravenous route. The quantities to be administered will obviously vary with each disease and patient, but one of the best guides is the urinary output. For many years clinicians have recognized that operating on a patient with an inadequate urinary output is associated with a formidable mortality.

2. *Correction of vitamin deficiencies* seen in surgical patients involves primarily the crystalline, water-soluble vitamins B and C. This deficiency results because of the fact that there is no storage for these vitamins in the body and that a multitude of situations may occur in the surgical patient which will increase the excretion or loss of these vitamins. Among these conditions are sepsis, increased metabolism, jaundice, vomiting, diarrhea and intestinal fistulas. Added to this burden of a depleted vitamin reserve is the problem of the increased vitamin requirement. Phys-

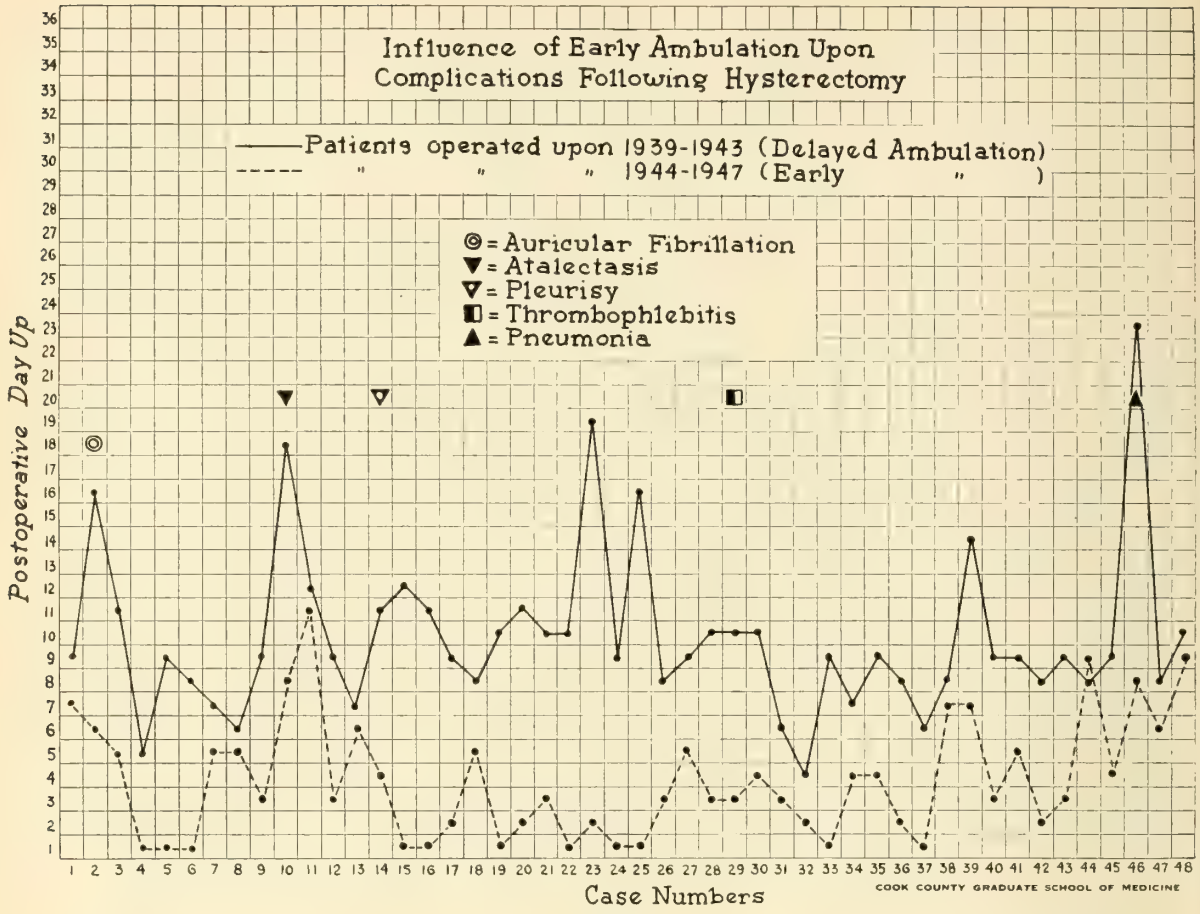

Fig. 4.

iologists are now agreed that thiamin, riboflavin and niacin are essential in carbohydrate metabolism. The experimental work on wound healing has conclusively shown that ascorbic acid is essential to the production of intracellular collagen between fibroblasts. The necessity for vitamin K in the synthesis of prothrombin by the liver is an outstanding contribution of the past decade. Fortunately, all of these vitamin deficiencies can be quickly rectified by the availability of a potent crystalline vitamin for intravenous use. They are to be included in any program wherein intravenous or subcutaneous fluids are required.

3. *Correction of protein deficiencies.*—The importance of protein metabolism was first recognized by surgeons who perforce were made cognizant of it by virtue of the fact that if the protein deficiency did not exist before operation it would only become aggravated after the operation. We have come to recognize that laboratory methods alone are inadequate for the recognition of this protein deficiency; for example, dehydration or infection could produce both a false elevation in the serum globulin fraction of the protein and therefore a falsely elevated total protein. We are also cognizant of the inaccuracies of many methods for determining blood proteins. Actually, the only accurate means at hand would be to determine the plasma volume by the injection of a dye together with the protein concentration. However, this method requires rather elaborate laboratory facilities and is not applicable to routine clinical use. From the clinical standpoint, the surgeon must learn to anticipate protein deficiency without the benefit of biochemical methods. We have taught therefore that hypoproteinemia can be assumed to exist in any surgical disease characterized by:

(a) Decreased intake of protein, such as from dietary restrictions and obstructions of the esophagus and pylorus.

(b) Decreased absorption of protein, such as

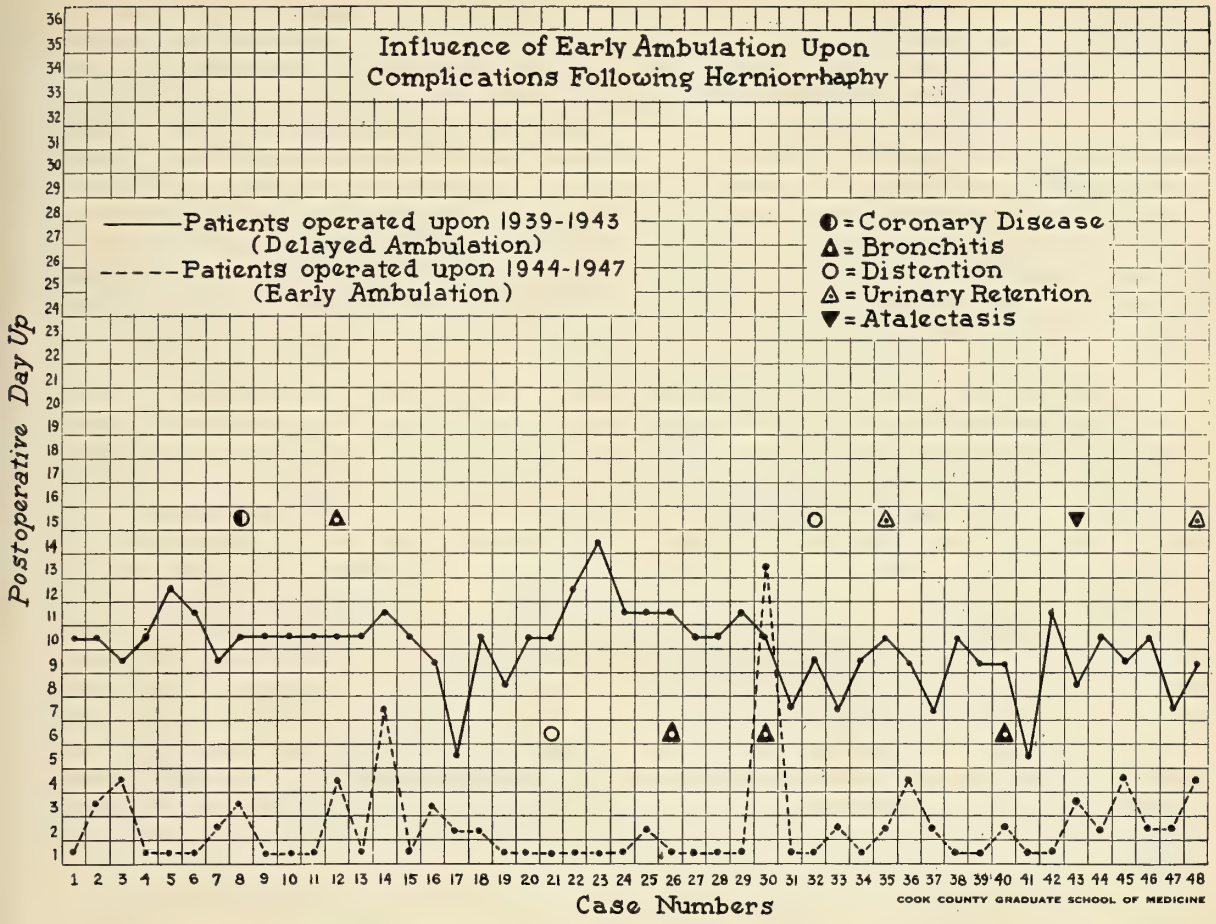

Fig. 5.

from any ulcerations of the gastrointestinal tract, carcinoma, obstructions or fistulas.

(c) Decreased synthesis of protein, such as from any of the various types of liver damage seen in icterus, cirrhosis and hepatitis. It is commonly agreed that the liver is the most important site for the synthesis of serum albumin.

(d) Increased loss of protein, which is particularly characteristic of surgical diseases such as burns, hemorrhage, peritonitis, abscesses, empyemas, diarrheas, vomiting, et cetera.

(e) Increased requirements for protein, such as in any fevers, hyperthyroidism and pregnancy.

The correction of protein deficiencies can be accomplished by one of four means:

(a) *Oral protein* which is still the simplest, the least expensive and the most widely applicable. If relying upon natural foods for sources of protein, one can augment this by insisting upon six feedings a day spaced through the twenty-four-hour period instead of the three meals a day conventionally given within a ten-hour period. In many instances the use of natural protein limits the quantity ingestable because of bulk. These can be supplemented by various digests now available, some of these being more palatable than others.

(b) The second method of correcting protein deficiencies involves the use of parenteral amino acids. Since the original report, barely ten years ago, a large number of casein digests have been developed for intravenous use which are safe, well tolerated and capable of producing positive nitrogen balance. It is important to remember that these solutions have to be well protected by carbohydrate intake lest they be used as a source of calories. It is also worth noting that the quantities of amino acids necessary to produce the desired results exceed those generally recommended.

We have found that serum protein levels frequently do not reflect the improvement, and prob-

ably weight gain is as good a criterion as any. Whenever possible, intravenous amino acids should only be relied upon to supplement protein taken by mouth. However, when oral feeding is impossible, this means may prove to be a life-saving measure.

(c) The use of plasma has now been largely given up because it has been found to be far too expensive a means of correcting protein deficiency. It has been found that approximately 2,000 c.c. of plasma would be necessary to produce a rise of the protein of 1 gm. per 100 c.c. This would be formidable from the point of view of replacement and purchase. We have found plasma protein usually produces a fall in protein concentration rather than a rise and have reserved the use of plasma chiefly for emergency treatment of shock and burns. The incidence of homologous serum jaundice attributable to pooled plasma has more recently led to its disuse except in the most dire circumstances.

(d) The use of whole citrated blood has delighted us with its clinical effectiveness. We administer here not only some 18 gm. of plasma protein with each unit, but also 75 gm. of hemoglobin and many other factors concerned with resistance to infection. So convinced have we become of the efficacy of blood transfusions in the management of the surgical patient that we have made it a dogmatic ruling to precede all of our major gastrointestinal surgery with a minimum of 2,000 c.c. of whole blood. This we prefer to have administered before operation when the patient's metabolism is such as to take fuller advantage of it.

Good clinical judgment for the preparation of the patient for elective surgery would be to combine the use of oral protein with intravenous amino acids and whole blood transfusions. This we have found most practical, for here we have a means of correcting tissue protein and circulatory protein losses.

4. *Correction of anemia.*—An underlying anemia probably exists more often than we are capable of recognizing. In many instances of hemorrhage, there is a compensatory dehydration which will falsely elevate the blood count just as it may falsely produce a rise in the serum globulin. Such a situation is frequently demonstrated by repeating the blood count or hematocrit after the administration of fluids. The presence of anemia demands even more frequent transfusions of whole blood than when there is plasma protein deficiency alone. We know of no criteria for determining the quantity of blood that will be necessary. On the other hand, we know of no reason for limiting the number of transfusions. Therefore, the quantity of blood to be administered to the anemic patient is that amount which will produce a satisfactory blood picture and clinical condition, whether this means one or twenty transfusions.

5. *The use of transverse incisions* is to be preferred to vertical incisions in patients in whom early ambulation is contemplated. The reason for this is that the transverse incision has a lower incidence of evisceration, nerve destruction and herniation. Although this point cannot always be followed, the principle is nevertheless a good one.

6. The use of *interrupted sutures* we consider important in this program, whether it concerns the wound or a gastrointestinal anastomosis. By this means we believe the lines of tension are more equally distributed and there is less narrowing of the lumen. We consider the use of interrupted sutures of more importance than the type of suture used.

7. The use of *permanent sutures* would seem to have a definite advantage, in that they produce less tissue reaction than catgut sutures, attain a maximum tissue strength which is maintained indefinitely and are less apt to become infected. We have preferred silk and stainless steel wire. Others prefer cotton. We are quite interested in the fact that quite a number of men who practice early ambulation have done so with the use of catgut sutures in the wound.[18]

8. *Wound infections are cautiously avoided,* and this usually implies the avoidance of trauma and hematoma. In operations such as those on acute gangrenous appendices with soilage, we have found very helpful the insertion of a drain down to but not through the peritoneum as a means of minimizing wound infections.

The need for chemotherapy in some of these patients does not necessarily mean discontinuation of the early ambulation program. Although sulfonamides still have a place in chemothera-

peusis, we prefer at present in most laparotomies a course of penicillin medication whenever an actual infection exists or prophylactically. In the colon surgery cases the nonabsorbable sulfonamides—sulfasuxidine or sulfathalidine—are used in conjunction with penicillin because of their local bacteriostatic effect. No sufficient data for the specific need of streptomycin in some of these cases have as yet been obtained. We found 20,000 units of penicillin at three-hour intervals to be a sufficiently large dose for most of the patients in our series. In some instances, a larger dose than 20,000 units of penicillin might be necessary, but this is best determined by running a sensitivity test on the causative organism.

9. *Patients should be informed* before operation that they are to be ambulated early. This will allay apprehension, procure better co-operation, and make the patient more interested in his convalescence.

10. *The choice of anesthetic* is important, and wherever possible we prefer spinal anesthesia because it provides us with a more co-operative patient.

Advantages of Early Ambulation

The results of early ambulation as reported from many independent sources can now be determined from the observation of several thousand patients; the criteria for evaluation are clinical, with only a few animal experimentations to support such observations. However, the accumulated data are so unanimously in favor of early rising that a consideration of these advantages, even in the present theoretical stage, probably has much to support it.

Decreased pulmonary complications could be anticipated, for as Cutler and Hoerr[5] point out, 50 per cent of postoperative pneumonic complications occur in the first twenty-four hours, and 90 per cent within the first four days. If, as we now believe, the majority of these are atelectatic originally, then any maneuver which improves the cough reflex, the expectoration of mucus, an increased vital capacity and lung volume will minimize this complication. McMichael and McGibbons[14] have reported a 340 c.c. decrease in lung volume as a result of recumbency, and a 780 c.c. decrease in supplemental air as the result of elevation of the diaphragm. Churchill and McNeil[4] observed the effect of cholecystectomy and appendectomy upon the vital capacity in patients kept in bed after operation as was customary in 1927. Leithauser[10] repeated these studies in 1943 in patients with similar operations, but obliged them to ambulate early after operation. The diminution of vital capacity postoperatively was less in degree in Leithauser's series and the return to normal was materially hastened. Blodgett and Beattie[2] noted a decreased incidence of atelectasis from 6.3 per cent to 4.3 per cent as the result of instituting ambulation at the Peter Bent Brigham hospital. However, as noted by Leithauser,[11] not only early ambulation but hydration, medication, anesthesia, choice of incision, and distention are also factors in the production of atelectasis.

Decreased vascular complications appear to have considerable experimental evidence to support it. In dogs ambulated early there was a 250 per cent increase in the flow of blood from the inferior vena cava. Smith and Allen[19] noted a prolonged circulation time in bed-ridden postoperative patients by the second postoperative day, which is prolonged 50 per cent above preoperative controls by the tenth postoperative day. Actual decrease in circulation time from 1.5 to 4.5 seconds have been reported in patients following earlier ambulation. Bed rest tends to pool blood in pelvic and calf veins; rest in bed tends to collapse veins, especially if pillows are used, and this leads to intimal injury. Thus the combined influence of stasis and intimal damage are present precipitating thrombus formation. Further investigative evidence apropos of this phase of the problem is the observation of Snyder[20] that recumbency leads to a decreased cardiac output, and of Mayerson and Burch[13] that recumbency is associated with a venous pressure and blood volume deficit.

Clinical results are somewhat more equivocal. Dahl-Iverson[6] reported a drop in the incidence of phlebitis, thrombosis, and embolism from 3.5 per cent to 0.58 per cent with the institution of earlier ambulation. Von Jaschke[3] reported 300 patients treated by delayed ambulation with a 2 per cent incidence of thrombosis and a 1 per cent incidence of fatal emboli. In 387 patients treated by early rising, the incidence of thrombosis dropped to 0.5 per cent and there were

no fatalities from emboli. Blodgett and Beattie[2] found a rise in the incidence of phlebitis with early ambulation from 1.8 per cent to 3.2 per cent, but expressed doubt as to the value of their observation in view of the length of their series. Burch and Fisher[51] reported two fatal emboli in 2,827 individuals ambulated early, one on the tenth postoperative day and one on the sixty-seventh postoperative day. In our series there was a significant decrease in the incidence of thrombophlebitis as the result of earlier activity, but as to phlebothrombosis, we have not seen a decided trend. Possibly the prophylactic use of anticoagulants or femoral ligation may prove more decisive factors than the use of early rising.

Since the preparation of this paper we have seen two cases of fatal pulmonary embolus in patients ambulated early. One occurred in a patient who was treated with dicumarol for a phlebothrombosis following an abdomino-perineal resection. This produced massive bleeding from the perineal wound, and ten days after discontinuance of the dicumarol the patient expired from a pulmonary infarction. Another fatal episode occurred in a patient twenty days after the closure of a perforated carcinoma of the sigmoid which had produced a purulent peritonitis. This would indicate that the problem of thromboembolic disease is still a challenge.

Decreased wound complications seem to be characteristic of early ambulation. This is possible by virtue of the decreased lag period in the wounds healing under the influence of early walking which in turn is attributed to increased blood supply, more efficient lymphatic drainage, and less atrophy due to disuse. Newburger[15] found that the abdominal wounds of rats forced to exercise early attain a higher tensile strength earlier than did the control rats allowed to rest. Blodgett and Beattie[2] reported a drop in the incidence of wound infections from 5.7 per cent to 2.7 per cent as the result of ambulation, and of evisceration from 2.8 per cent to 1.1 per cent. Leithauser and Bergo[12] reported only one evisceration in 900 cases of early rising. A decreased incidence of postoperative hernia as the result of earlier ambulation has been noted by Powers,[16] Ashins,[1] Schafer and Dragstedt,[18] and Elman and Akin.[8]

Decreased postoperative fever both in degree and duration has been reported by D'Ingianni,[19] by Schafer and Dragstedt,[18] and was noted in our own series. The mechanism accountable for this is not apparent.

Fewer catheterizations might be anticipated and were so reported by D'Ingianni.[7] However, we have not seen a significant decline in our own experience.

Fewer hypodermics have been claimed.[7] Early rising is attended by a diminution in wound pain, which would therefore lead to the use of fewer analgesics.

Improved gastrointestinal function has been claimed and is manifested by an earlier return of appetite, fewer gas pains, less distention and ileus, need for fewer enemas, and a decreased period of postoperative starvation. A claim has also been made for fewer adhesions with earlier ambulation due to the more frequent change in the position of the viscera.

Decreased incidence of decubitus ulcers is logical because of the improved nutrition and earlier relief of pressure effects from continuous supine position.

Earlier return of strength and a sense of well-being is clearly manifested in the early rising patients. It is not unusal for a patient to shave himself three or four days after a gastric resection. The psychological advantage is worth attaining for the patient who gets out of bed early assumes that he is doing well, otherwise he would not be allowed out of bed.

Improved liver function and nitrogen balance has been reported for patients ambulated early after herniorrhaphy[20] compared to controls. Early ambulation did more for the attainment of a positive nitrogen balance than did a variety of methods for increasing nitrogen intake in bed-ridden patients.

Economic advantages of early ambulation are accrueable to the patient, the hospital, and the employer. The period of disability is lessened and, therefore, the financial deficit is minimized for the patient. The number of days of hospitalization after operation is materially decreased as is the amount of nursing care, thereby easing the problems confronting most hospitals throughout the country today. The earlier return of the

employee to productive efforts is a boon to industry.

Contraindications to Early Ambulation

No discussion of early ambulation would be complete without a consideration of possible contraindications. Failure to recognize that not all patients can be ambulated early has probably led to the abuse and disuse of this program in the past. Each patient should be individually evaluated, and if any of the following extenuating factors are present, final judgment may well be to defer ambulation.

1. *Shock:* hypotension is aggravated by motion and the erect position.

2. *Hemorrhage:* because of the attendant shock and fear of encouraging more bleeding with motion.

3. *Generalized peritonitis:* because of the pain, distention, and sepsis.

4. *Unrelieved intestinal obstruction:* because of the distention and the resultant tension on wounds.

5. *Pulmonary infection:* because of tachycardia, dyspnea, toxemia.

6. *Wound evisceration or extensive wound infection:* tensile strength of wound is diminished.

7. *Severe toxic states:* irrational states such as are seen in thyroid crisis, sepsis.

8. *Cardiovascular complications:* ambulation would add to the load of a burdened myocardium.

9. *Extreme debility:* nutritional deficiencies.

10. *Severe anemia:* cerebral anemia aggravated in the erect posture.

Summary

1. The postoperative complications of 500 surgical patients after the performance of one of five standard surgical procedures (gastric resection, colon resection, cholecystectomy, hysterectomy and herniorrhaphy) were studied in relation to early or late ambulation.

2. There was a total of ninety-eight complications among 500 patients; twenty-eight of the complications occurred in the 250 patients ambulated early and seventy in the other half ambulated late, 11.2 per cent and 28.0 per cent respectively.

3. There was a total of thirteen deaths (included in the ninety-eight complications), of which all but one occurred in the group with prolonged bed rest.

4. Pneumonia not only occurred more frequently in the late risers but also was more often fatal.

5. Postoperative wound infections, thrombophlebitis, and distention showed a definite decline with early ambulation, whereas pulmonary atelectasis and cystitis did not.

6. A significantly shortened period of hospitalization was seen for each of the procedures when followed by early ambulation.

7. A detailed consideration of the prerequisites for early ambulation, its advantages, and contraindications is presented.

CALCIFIED NODULAR AORTIC STENOSIS

A Study of Eighteen Pure, Advanced Cases

THOMAS S. KEMP, M.D.
Duluth, Minnesota

The usual form of aortic stenosis is the calcified nodular deformity, where the oriface is reduced to a narrow slit-like opening, the leaflets having been made rigid by the deposition of calcium and fibrous tissue in the form of massive nodules with a fusion of the edges of the adjacent leaflets. This cardiac lesion deserves more emphasis than has been given it by most clinicians and pathologists because it represents a distinct entity that is unlike other valvular lesions in its course and manifestations and because it remains a subject of great dispute with regard to its etiology and pathogenesis. The present study was undertaken in an attempt to further elucidate the clinical picture that one might expect from this lesion.

Those interested in the controversial subject of etiology of calcified nodular aortic valvular disease should review the publications of Monckeberg,[7] Sohval and Gross,[11] Margolis, Ziellessin and Barnes,[6] Sophian,[12] Christian,[1] Clawson,[2] Clawson, Noble and Lufkin,[3] Dry and Willius[4] and Hall and Ichioka.[5]

TABLE I. INCIDENCE

	Number
Autopsies	2,987
Aortic stenosis, all forms	90
Aortic stenosis, pure and advanced	18
Hospital Admission	95,266

Material for Study

The studies of calcific aortic stenosis that have been carried out to date have for the most part included those of all degrees of intensity and combined with other valvular heart lesions. In a study of the clinical features of this lesion as is the primary purpose of this study, an inclusion in the series of valvular deformities besides aortic deformities would lead to confusion as one would not likely know which symptom or finding was due to which valve deformity; and, an inclusion of the milder degrees of stenosis would be undesirable because they seldom give rise to any complaints. Consequently, the cases that are reviewed in this study are those of calcified aortic stenosis considered to be sufficiently advanced to give rise to a definite clinical picture and free of any other valvular deformity considered sufficient to complicate the clinical picture. Eighteen such consecutive cases, all determined by autopsy examination, have been selected for study (Table I). During this period of 10 years a total of 2,987 autopsies were performed. Ninety of these were cases of calcified nodular aortic stenosis representing all degrees of deformity and all combinations of valvular lesions. There were 95,266 admissions to the hospital during this period.

Karsner reviewed 200 cases of aortic stenosis in which he reported the following distribution of cases:

Aortic stenosis and other gross rheumatic lesions	
No deformity	25
Slight stenosis	36
Moderate stenosis	9
Marked stenosis	21
	91
Aortic stenosis, pure	
No deformity	53
Slight stenosis	23
Moderate stenosis	10
Marked stenosis	23
	109

The 23 cases considered a marked, pure aortic stenosis in Karsner's series are probably comparable to the cases presented in this study.

TABLE II. AGE AND SEX
St. Luke's Hospital

Age	Male	Female	Total
20-29	0	0	0
30-39	1	0	1
40-49	2	1	3
50-59	1	1	2
60-69	1	1	2
70-79	6	0	6
80-89	4	0	4
90-99	0	0	0
Total	15	3	18

Age and Sex

Fifteen of our eighteen cases were in males (Table II). In Karsner's series there were 200 males and 144 females. Eight were found to be under seventy years of age while the remaining ten were seventy or over. The average age was sixty-three years. Karsner found calcified aortic stenosis to be three times as frequent among persons fifty years or more as among those less than fifty. Calcified aortic stenosis then is essentially a disease of old age; nevertheless, it does occur in the younger age groups and is recorded occasionally in the early twenties. The average age of other authors varies from fifty-two to sixty-five years.

Calcific aortic stenosis is a disease predominantly of males, having been found five times as frequently in males as in females in this series. There was no need for correcting these figures for the relative frequencies of men and women in our entire autopsy series as their

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota.

frequencies were very similar. Other authors report ratios ranging from 1.6 males to 4.5 males for each female.

TABLE III. SIGNS AND SYMPTOMS
(At time of last admission)

Clinical	Number	Percentage
Dyspnea	14	77
Orthopnea	10	55
Angina	10	55
Cough	7	39
Edema	7	39
Palpitation	3	16
Syncopé and Dizziness	3	16
Ascites	3	16
Cyanosis	3	16
Sudden death	2	11
No symptoms	2	11

Signs and Symptoms

A review of the signs and symptoms at the time of the last admission (Table III) revealed the most frequent symptom encountered and the first symptom to develop in most cases to be dyspnea or exertion, having been found in 77 per cent. It was frequently accompanied by some degree of orthopnea, especially as death was approached. Dyspnea can readily be explained as a transient episode of left heart failure. The heart during the period of gradual compensation through hypertrophy and dilatation to the increased demands laid upon it by progressively narrowing aortic valves, temporarily cannot cope with the demands of increased exertion until it responds through dilatation or until the exertion is removed. Ultimately, the time comes when the heart's capacity for compensation will have been reached and the dyspnea becomes permanent.

Angina pectoris was a complaint in 55 per cent of the patients when seen at the time of last admission. Particular emphasis must be placed on the symptom because it is undoubtedly the reason for the diagnosis of coronary disease in so many of the cases where angina occurs, neglecting entirely the possibility of a valvular disturbance. Angina is a symptom that rarely occurs in mitral stenosis or aortic insufficiency; consequently, when found accompanied by any organic heart murmur it should lead one to suspect calcified disease of the aortic valves. The explanation of angina pectoris as it occurs in aortic stenosis is not settled with any certainty. It was once thought that it might be due to narrowing of the coronaries. Karsner, as late as 1947, found some degree of coronary sclerosis in all his cases and believes this to be a factor in the production of angina. Most investigators, however, have been unable to find any increased incidence of coronary sclerosis in these cases; in fact, Dry and Willius concluded that the degree of sclerosis occurred in inverse proportions to the degree of aortic stenosis. Clawson suggested that the calcific nodules may be impinged on the coronary ostia but this has never been verified. Contratto and Levine offer an explanation based on physical principles. They suggest that the increased velocity of the blood flow past the coronaries serve to suck the blood from the coronaries, thus reducing their inflow. Even though they are able to compensate by dilating, they are still not able to supply sufficient blood for the tremendously increased demands in this condition with the ultimate result of a myocardial ischemia and consequent angina. This is purely theoretical and has never been proved. Green held the view that aortic stenosis decreased the coronary blood flow during systole by causing a relatively higher degree of resistance in the coronary bed during the systolic contraction of these powerful hypertrophied hearts. His cases with angina had larger hearts than were found in the others. Another explanation offered at this time is based on two established facts: that the systolic contraction period of the cardiac cycle is prolonged in aortic stenosis and that coronary filling occurs during diastole. The diastolic phase of the cardiac cycle is shortened correspondingly to the lengthening of the systolic phase at a given heart rate with the result that the coronaries are incompletely filled during this short diastolic phase.

TABLE IV. CORRELATION OF ANGINA WITH CORONARY SCLEROSIS AND HEART WEIGHTS

Group A	Average Heart Weight	Coronary Findings	Number Cases
No angina (8 cases)	577 grams	Grade II sclerosis	3
		Grade I	3
		Grade 0	2
Group B Exertional angina (5 cases)	603 grams	Grade II	2
		Grade I	3
Group C Sudden severe pain (5 cases)	621 grams	Grade IV and thrombosis	1
		Grade II	1
		Grade I	2
		Grade 0 and embolism	1

The cases of angina in this series were studied and correlated with the weight of the heart and the size of the coronary lumina (Table IV). In those cases not demonstrating angina, the degree of sclerosis did not differ appreciably from those that complained of exertional angina. In only two of the five patients who complained of excrutiating precordial pain was there any coronary findings to account for it. One had a severe grade of coronary sclerosis, a coronary thrombosis and myocardial infarction. The other had a coronary embolism. The coronary ostia were patent in all of the cases. There appears to be a significant difference in the heart weights among the three groups. From this study one can conclude that in most cases of aortic stenosis, disease of the coronary vessels and their ostia cannot account for the common complaint of angina. There may be a greater frequency of angina in the heavier hearts.

Syncope and dizziness are of considerable diagnostic significance when they occur; however, they are not frequently encountered in this series, where they were only 16 per cent of the total. These symptoms are believed to be due to impairment of cerebral circulation because of the inability of the aortic pressure to fill the cerebral vessels adequately.

Sudden death, that is, a sudden turn for the worse in a previously stabilized individual with death following in a few hours, occurred in two of our patients (11 per cent). One, a sixty-three-year-old female, was awakened from sleep with profound dyspnea. She was brought

immediately to the hospital where she was found to be unresponsive, cyanotic, and severely dyspneic, dying thirteen hours after admission. Her coronary vessels were entirely normal. The second case was an eighty-four-year-old male with a previous history of aortic valvular disease, who suddenly was overcome with acute cardiac distress, dying twenty-one hours after admission to the hospital. His coronaries were found to have grade IV sclerosis with a thrombosis and myocardial infarction. The aortic valvular disease was considered an incidental finding at the necropsy. Similar percentages have been found by other investigators, the average of all other figures being 11.5 per cent. The majority of reported cases have occurred during chronic congestive heart failure with no immediate cause demonstrable. The possibilities suggested to explain this occurrence are coronary thrombosis, a myocardial ischemia producing heart block or ventricular fibrillation, and sudden cerebral anemia.

TABLE V. PHYSICAL FINDINGS AT TIME OF LAST ADMISSION

Findings	No.	Percent
Systolic aortic murmur	13	72
Aortic diastolic murmur	3	16
Mitral systolic murmur	7	39
Precordial systolic murmur	4	22
Mitral diastolic murmur	4	22
Pulmonary congestion	13	72
Pleural effusion	3	16
Hepatomegaly	4	22
Cardiac enlargement	11	61
No findings	0	0
Positive findings	18	100

Physical Findings

The most frequently and most characteristic physical finding (Table V) is the murmur heard over the entire precordium but loudest over the aortic area, i.e, the second right interspace, which if heard alone is pathognomonic of aortic stenosis. It can be transmitted along the right manubrial border and classically it is transmitted in the right or in both carotid arteries, and in the right and sometimes both subclavians. When extreme it can be heard at some distance from the body. The murmur is a harsh, rough, saw rasping murmur when the stenosis is of an advanced degree. This murmur was found in 72 per cent of the eighteen cases presented. Karsner has been able to find no difference in the incidence of murmurs with the varying degree of stenosis; however, he did find a relation between the quality of the murmur and the degree of stenosis. The loud, harsh, rough murmur was heard most frequently in cases of marked and moderate stenosis, with a soft blowing aortic murmur in cases of slight to moderate stenosis. An aortic thrill will frequently be felt in advanced cases, especially when the patient is examined leaning forward with the flat of the hand over the aortic area during full exhalation. With marked decompensation the thrill will often disappear and the murmur loses its harshness and intensity.

The absent or greatly diminished second aortic sound is perhaps the most single confirmatory sign. It may sometimes be replaced by a soft blowing diastolic murmur which, unfortunately, is not a common finding, Reich[8] having found it absent in 9 per cent of cases of pure aortic stenosis. When the second aortic sound is absent the aortic stenosis will most certainly be of a severe grade with extreme rigidity of the aortic cusps to account for the absent second sound.

An aortic diastolic murmur was heard in 16 per cent of our cases. This figure is low in comparison with other published results, Reich[8] having reported it in 40 per cent of the cases in his series. It is usually assumed to indicate some associated aortic insufficiency.

An apical systolic murmur was found in seven cases (39 per cent). When present it can be assumed to mean either a mistaken identity, a relative mitral insufficiency from dilated left ventricle, or organic mitral insufficiency although no such cases were included in this series.

Presystolic and diastolic mitral murmurs were heard in four of twenty-two cases. They may mean in the cases presented here an Austin Flint murmur from accompanying insufficiency or possibly a mistaken identity. When heard otherwise it usually means an associated mitral stenosis. In Karsner's 200 cases of mixed valvular lesions he found eighteen presystolic mitral murmurs of which fifteen were proved at autopsy to be due to mitral stenosis. In eighteen cases of diastolic mitral murmurs nine were proved to have mitral stenosis.

Failure to localize the murmur to any particular area, employing the term "precordial murmur" is generally recognized as a common finding (22 per cent in this series). The reason for the failure of this murmur to localize is not known.

The classical pulse of an aortic stenosis is the "pulsus tardus et parvus." The recorded pulse wave will show a slow rise and fall with an intervening plateau, the entire amplitude being greatly reduced. There may be a slight interruption near the summit, the anacrotic pulse, or it may have a bifid apex, the so-called pulsus bisferiens. Clinically, there is a definite delay in the rise of the pulse with a peak occurring later than is the case in a normal pulse. This characteristic pulse has not been frequently found by most authors, perhaps because of the combinations with varying degrees of insufficiency as most aortic stenoses seem to have.

Aortic stenosis does not affect the systolic blood pressure and it will either decrease the diastolic pressure slightly or not at all. The pulse pressure, consequently, is normal or slightly increased. Blood and pulse pressures are not informative then because of the little effect that aortic stenosis has on them and because of the many other variables that are usually present which do affect the blood pressure.

Cardiac enlargement was demonstrated in eleven cases or 61 per cent at the time of the last admission to the hospital. The heart is characteristically enlarged to the left and downwards as far as the sixth and even the seventh intercostal spaces. The heaving apex may be seen four or five cm. in breadth in the intercostal spaces; however, when completely compensated the apex is not demonstrably enlarged.

The electrocardiogram shows nothing specific for this condition. It demonstrates left ventricular strain by left axis deviation and more so by negativity of the T-waves in leads I and I and II. Evidence of delayed conduction

are seen occasionally, including bundle branch block, interventricular block, or auricular-ventricular block of various degrees ranging from prolonged A-V conduction to complete dissociation. This delayed conduction has been explained on several bases: extension of the calcific process into the bundle of His and myocardial ischemia. Friedberg and Sohval[11] felt it unlikely that an extension of the lesion is the explanation because this extension cannot be demonstrated on specimens, because the disturbances vary so much for a fixed lesion and because it would not involve a single bundle.

TABLE VI. DURATION OF SIGNS AND SYMPTOMS

History of	5 years or more		2-5 years		6 mos. to 2 years		1 mo. to 6 mos.		Last mo.

Syncopé	1	6	1	6	2	11	2	11	3	16
Ascites							1	6	3	16
Cyanosis									3	16
Sudden death									3	16
No symptoms	13	72	11	61	5	28	5	28	2	11
Positive symptoms	5	28	7	39	13	72	13	72	16	89

*The percentages in this table were calculated on the basis of the entire series of eighteen as the histories of the duration of the complaints whether from the single last admission record or from a combination of old records are reasonably accurate.

The use of fluoroscopy and roentgenograms in the clinical diagnosis of calcified aortic stenosis is fast becoming of great importance. One might expect from observing the amounts of calcium in some of these lesions that they could easily be demonstrated by roentgen rays and would appear on the fluoroscopic screen as dancing shadows over the aortic area. By the use of special technique including a small fluoroscopic aperture approximately two inches square, a screen of high intensity with the patient in the slight right anterior oblique position, the shadows can be demonstrated by fluoroscopy. One must accommodate satisfactorily and look through the heart, watching for dark irregular shadows along the oblique line between the apex and base which have a characteristic dancing motion between systole and diastole.

The patient then can be rotated to the left anterior oblique and the aortic differentiated from the mitral calcification. Sosman[13] reports that most of the valves proved to contain calcium at autopsy are demonstrable roentgenoscopically. He considers it by far the most important and valuable finding in differentiating aortic stenosis from other conditions causing left ventricular hypertrophy. He found calcification in the aortic valves in fifty-nine patients by x-ray methods. Several of these came to autopsy and in all of them except one, massive calcium deposits were found in the aortic valve while the exception had calcification in the coronary vessels. He has seen many cases of minimal calcified aortic stenosis come to autopsy when the deposits were overlooked by x-ray study. Reich[8] states that the correct clinical diagnosis can be almost doubled with the use of x-ray.

Diagnosis

A positive diagnosis of aortic stenosis rests ultimately upon the recognition of one or more criteria, the characteristic murmur which is the most significant physical finding when present and the fluoroscopic demonstration of aortic calcification. Although the presence of a thrill is significant, to demand its presence for a diagnosis would lead to failure to recognize aortic stenosis in the majority of cases, especially in the earlier ones.

A combination of the above absolute findings with a negative Wassermann, negative history of lues, and absent peripheral signs will rule out aortic insufficiency. Calcified aortic stenosis is very frequently confused with arteriosclerotic heart disease where an electrocardiogram may be of no help. The murmur and x-ray findings are all that is necessary to differentiate.

The clinical diagnosis can be made in mild cases with less accuracy. Willius reports that a diagnosis of mild aortic stenosis, grade I or grade II intensity can be made on the bases of a rough, moderately loud systolic murmur over the aortic area with poor transmission, absent thrill, unaltered A_2 an aortic diastolic murmur present only rarely, peripheral pulse and pulse pressure unaltered, frequent demonstration of small amount of calcium by special roentgenoscopic technique, and either no or slight left axis deviation on electrocardiograms.

Course and Prognosis

The patient with calcific aortic stenosis is well for a long time before the onset of symptoms. One of the striking features of this disease is the ability of the heart to compensate for this gradually developing lesion over a period of many years without showing clinical evidence of myocardial insufficiency. These hearts hypertrophy to enormous proportions before decompensating. The lesion is often picked up at an insurance examination or on a routine checkup and in a few cases is not even suspected during life, only to be found at the autopsy after death from other causes. The patient may have known of the existence of an aortic stenosis with a typical murmur for many years and feel well all this time, but when he fails, he fails rapidly, death not being far off, usually not more than one or two years at the most. Contrast this to a mitral stenosis where the individual's life expectancy is several years reduced and where there is decompensation from which the patient will recover and fail repeatedly over a period of many years. The same is true of tricuspid stenosis.

A study of the course of the disease was made by following the signs and symptoms and physical findings over a number of years before death at intervals, of five or more years, two to five years, six months to

two years, one to six months, and the last month before death.

A small number of the patients (seven or 39 per cent) gave a history of at least one symptom referable to the heart two years or more preceding death. Most of these cases had some exertional dyspnea indicating that there were transient episodes of left heart failure with exertion; transient, because the pulmonary congestion was overcome by the unusual ability of the heart to compensate through further dilatation and hypertrophy. Finally, the interval is reached between six months and two years when the ratio of symptoms to nonsymptoms is almost reversed. From that point on 72 per cent of the patients had heart complaints which were chiefly those of left heart failure until shortly before death when symptoms and signs of complete heart failure were apparent in a few cases.

A study of the progression of physical findings was handicapped by the small number of patients with previous hospital admissions covering a number of years before death, and, as a consequence, the results at these longer intervals will not be of any great statistical significance, but will be mentioned, nonetheless.

Records of five years or more before death are available in two cases. One followed a course characteristic of the disease. The patient was a female, fifty-five years of age at the time seen about seven years before death. At this time she was admitted because of a chronic cholecystitis and cholelithiasis. There were no symptoms referable to the heart, but the patient was found to have a heart enlarged 12 cm. to the left from the midline and a harsh systolic aortic murmur transmitted into the great vessels of the neck. When seen next, seven years later, and just twelve hours before death, she was in a state of acute cardiac decompensation giving a history of increasing exertional dyspnea for only one year.

The course as followed through physical findings proves to be quite similar to that mentioned above with regard to signs and symptoms. In every record examined, irrespective of the time before death, there was at least one physical finding, usually either a heart murmur or cardiac enlargement or a combination. It is of striking significance that the characteristic murmur of aortic stenosis was heard in 60 to 72 per cent of cases where records for less than five years before death were available, this percentage remaining almost constant for any given interval. Physical evidence of left heart failure, temporary or otherwise, was found at all times in the bare majority of cases, while evidence of complete heart failure was present only terminally and then only in a small number.

TABLE VII. DURATION OF PHYSICAL FINDINGS

	5 years or more		2-5 years		6 mos. to 2 years		1 mo. to 6 mos.		1 mo. or less	
Hospital Records	2		5		10		13		18	
Physical Findings	No.	%	No.	%	No.	%	No.	%	No.	%
Systolic aortic murmur	1	50	3	60	7	70	9	69	13	72
Diastolic aortic murmur			1	20	1	10	1	7	3	16
Systolic apical murmur			3	60	4	40	6	46	7	39
Diastolic apical murmur	1	50	3	60	3	30	4	41	4	22
Systolic Precordial murmur	1	50	2	40	2	20	3	23	4	22
Pulmonary congestion	1	50	3	60	5	50	6	46	13	72
Pleural Effusion									3	16
Hepatomegaly							3	23	4	22
Cardiac Enlargement	2	100	3	60	6	60	8	61	11	61
No findings	0		0		0		0		0	
Positive findings	2		5		10		13		18	

*Percentages on this Table are based on the number of records available at that particular time category.

These clinical findings tend to confirm the generally accepted belief that the symptoms are held in abeyance for many years, but once complete failure occurs the end is near at hand, usually within six months or less; in fact, complete failure seems to be followed so rapidly by death in most cases that physical evidence has become apparent in only a few. The majority of patients with congestive heart failure respond poorly to therapy.

Pathologic Anatomy

A study of the necropsy findings (Table VIII) reveals that calcified aortic stenosis was present in advanced degrees in 100 per cent of the cases as this was the basis for the selection of the cases. Evidence of chronic congestive heart failure in the form of chronic passive congestion of the liver, spleen and kidney and lung with its terminal complications of bronchopneumonia, pulmonary infarcts and acute gastroenterocolitis was present as a moderate to severe degree in all of the cases. It was considered as primarily responsible for death, however, in thirteen or 72 per cent of the cases. Death from other causes was found in five cases and even in these cases aortic stenosis and congestive heart failure may be assumed to have been a factor. These were the result of a coronary thrombosis and myocardial infraction, a coronary embolism from a broken off piece of the calcified valve, a car accident with complicating pneumonia, and two cases following surgery, one a transuretheral resection of the prostate for benign hypertrophy with exsanguination and the other for surgery on an advanced bladder carcinoma. These figures are not similar to those of other authors. Reich[8] found death in only seven of twenty-two cases of aortic stenosis or 32 per cent as explainable by congestive heart failure or pulmonary edema. However, he has six cases of bronchopneumonia as the cause of death. We considered most cases of bronchopneumonia as a terminal event complicating the congestive heart failure which was considered the primary cause. Many authors present much lower figures varying from 30 to 50 per cent but one must keep in mind that their cases of aortic stenosis were not restricted.

Clinical Diognosis

The diagnosis of calcified aortic stenosis was made clinically in 33 per cent of the cases (Table IX). This figure is not meant as adverse criticism of the clinicians of this hospital; as a matter of fact it compares rather favorably with the figures of other institutions. Karsner's study of the figures of the Cleveland City and University Hospitals showed diagnosis of aortic stenosis in thirteen or 23 cases of marked stenosis or an average of 55 per cent. In 33 cases of slight and moderate stenosis a correct diagnosis was made in ten cases or 30 per cent. The chief source of confusion seems to lie in differentiation of arteriosclerotic and hypertensive heart disease from calcific aortic stenosis as the diagnosis of the former was made exclusively in 33 per cent. Granted that this diagnosis was correct in two cases it was made entirely to the exclusion of aortic stenosis. Another source of error was the confusion of aortic stenosis with other valvular disease when none actually existed.

The diagnosis of calcified aortic stenosis is not an easy matter when purely physical signs are used, especially in comparison with other forms of heart disease, e.g., aortic insufficiency and hypertensive heart disease. In the latter conditions accuracy is much greater, thanks to the instruments and diagnostic methods of precision that are available. There is but little question that with the more widespread use of roentgenoscopic procedures the diagnosis of aortic stenosis will reach a higher degree of accuracy.

Therapy

One might well have raised the objection to the necessity of making an accurate diagnosis that it really makes very little difference what diagnosis is made because the treatment employed will be the same for all cases of cardiac decompensation regardless of the cause. This same objection was once raised to diagnosing accurately congenital heart disturbances; however, with the development of surgical means of correcting certain of these anomalies the practical importance of an accurate diagnosis is at once realized.

We are now just entering into an era of great advancement in cardiac surgery. The day may well come in the near future when these aortic lesions as well as other cardiac lesions will be amenable to surgery. Only recently a technique has been devised by Smithy[11] which can be used in the correction of aortic and mitral stenosis. Employing a specially devised valvutome he successfully incised the aortic valves of experimental animals through an aortic approach, later extending the experimental work to an approach through the ventricle and auricles themselves. The culmination was reached when the procedure was performed in human patients with very encouraging results both from a surgical and a clinical standpoint.[10] Certainly, with the realization that selected cases of aortic stenosis will be amenable to surgical correction in the not too distant future, the importance of accurate diagnosis is imperative and must improve over the 33 per cent as found in this series.

TABLE VIII. PATHOLOGIC DIAGNOSIS

	No.	Per Cent
1. Calcified aortic nodular disease, grades III and IV	18	100
2. Chronic passive congestion, congestive heart failure, moderate to severe	18	100
3. Terminal pneumonia	7	39

History of Medicine In Minnesota

NOTES ON THE HISTORY OF MEDICINE IN COTTONWOOD COUNTY

L. L. SOGGE, M.D.
Windom, Minnesota

Thoughts of the early pioneer doctors of Cottonwood County bring to mind the story of the hardships and self-denial of all of the early settlers, and particularly the fatigue and exposure endured by the physicians, who in faithfulness to their professional obligations were on duty at all hours of day and night, in all weathers, traveling over trackless prairies, fording unbridged streams. The history is rich in anecdotes of their courage, resourcefulness and loyalty, under conditions that, viewed from this day of ease in communication and transportation, of wealth of equipment and of diagnostic and therapeutic aids, seem almost incredible. As a rule, it may be said that almost without exception those physicians were men of ability in their day and that they had a high sense of honor. Many a pioneer, during illness of himself or of some one dear in his family, felt that in the doctor's hands there was safety, and had faith that the best that could be done would be accomplished.

Cottonwood County, created by the Legislative Assembly of the Territory of Minnesota on May 29, 1857, was organized officially on July 29, 1870, when the county officers met at Great Bend, long since vanished, which was the first county seat. In the same season the first school of the county was started in that community. Although settlers came early into the county, it was not until 1871 that important development of the region began. The rigors of pioneer life were severe, transportation was extremely difficult, the Civil War took the sturdiest and youngest of the men from farms and businesses, Indian scares in 1862 frightened away many settlers who did not return until several years later, and recurring plagues of grasshoppers for some years were powerful deterrents to settlement. In 1870 the county had a few small hamlets or villages and a total population of 543. In 1871, the first great boom year of the county, came the railroad, which now is part of the Chicago and Northwestern system. On June 20, 1871, the village of Windom, destined to become the county seat, was platted on the east bank of the Des Moines River, near the line of the railroad. In July, when the first locomotive puffed into Windom, the place was ready for business: religious services had been held and social diversion organized; there were a community well, a hardware store and a bakery. That autumn, much wheat was shipped from the new settlement. The county had found itself.

The first physician who practiced his profession in Cottonwood County was Dr. Allen Smith, who arrived in Windom from Ohio on October 10, 1871. After two years in Windom he returned to Ohio, where his death occurred soon afterward.

Other physicians of the county, about some of whom little is known, and about others of whom considerable biographical information has been gleaned, are listed hereafter in alphabetical order.

Biographical Notes

Silas D. Allen (1826-1907) was born in Bradford County, Pennsylvania, on December 1, 1826. His wife, Lucy A. Allen, also was a native of Bradford County.

Dr. Allen obtained his early education in his native place and taught school there for a few years before studying medicine at the University of Michigan at Ann Arbor. Early in 1854, then twenty-eight years old, he decided to try his fortune as a gold miner in California, and on May 29 of that year he took passage on a sailing vessel at New York, en route to San Francisco by way of Cape Horn and the Pacific Coast. He remained in California until November 14, 1855, and was reasonably well paid financially for the hardships and varied experiences he passed through.

On his return from the Coast he settled, in 1856, in northeastern Iowa, near Lansing, and there farmed and practiced medicine for a number of years. Later he and his family moved to Carroll County, Missouri, where they stayed until 1874, when they came to Cottonwood County, Minnesota. The new home was a farm on the Valley Road, a mile from Windom; their first house, in which they lived six years, was built of logs. In 1880 Dr. Allen erected a good frame house, which still stands in 1948.

Always a lover of farming, and especially stockraising, Dr. Allen combined these occupations with the practice of his profession. Calls for his professional services were numerous, and he never failed to respond, day or night, generally going on horseback, which was the most practical and the quickest method in those days. He was a skillful physician, and his wisdom as counselor was much sought in serious cases by other physicians, who had full confidence in his skill and advice.

In September and October, 1875, there was a severe epidemic of diphtheria in the community, during which many were afflicted and thirteen children died. Dr. Allen successfully took care of most of the sick, and what a terrific strain it must have been! Those were anxious and trying days for both parents and physician. Early settlers still living in and near Windom who can remember anything about that epidemic say that the usual treatment then for diptheria was to have the patient gargle with a mixture of vinegar and pepper. In addition, in the care of children, the patient was covered completely with a sheet, and kerosene fumes then were forced under the sheet for the child to breathe. It is told that, under this treatment in some cases, the patients vomited up tube casts of membrane, and recovered.

After the medical practice act of 1883 was passed in Minnesota, Dr. Allen practiced under an exemption certificate.

The doctor was a broad-minded man of strong convictions, ever conscientious, and intolerant only of hypocrisy or graft of any nature. He always took an active interest in social conditions and public affairs, and worked for the betterment of the community. In 1901 Dr. Allen sold his farm and moved into Windom, retiring from active life. A great reader, he owned a splendid library of the best works, and in his later years devoted much of his time to his favorite authors.

Mrs. Allen died in 1902 in Windom. After her death the doctor lived alone most of the time until January, 1907, when he was stricken with an illness that ended in his death on April 4 of that year.

By his generous and sympathetic disposition, the doctor made many friends. He is remembered by many as one who seemed to think of his professional services only in terms of helping suffering humanity. After his death it was

found that his account books showed that thousands of dollars, which he never endeavored to collect, were due him for his work as a physician.

William Hulbert Banks (1874-1947), a native of Cottonwood County, was a son of one of the earliest pioneer settlers of the county. The following letter, written by Dr. Banks' son on December 27, 1947, to Mr. D. L. Keith, editor of the *Cottonwood County Citizen,* and published in that paper, tells the interesting story of the doctor's life:

William Hulbert Banks was born in Lakeside Township on October 14, 1874. His father, William Carr Banks, was one of the original settlers in the county, homesteading at Swan Lake in 1869, farming or residing in Windom until 1910. He hauled food supplies by ox team through blizzards from the rail terminal at St. James to Windom, when the hamlet was down to its last barrel of flour. He survived the grasshoppers to become a charter member of the "Idle Rich" club of court house square.

Bethia Odell Banks, Dr. Banks' mother, came to the county from Wisconsin to teach school and homestead. She was a leader in temperance, woman's suffrage, and educational advancement.

Dr. Banks attended his mother's Oak Grove school at the age of five to increase the school allotment. He graduated from the Wilder Academy and the Keokuk, Iowa, College of Physicians and Surgeons in the class of 1900. He practiced for twenty-one years in Wisconsin and Minnesota, and for twenty-four years at Yakima, Washington.

During one year, 1916-1917, Dr. Banks moved to Windom and conducted medical practice Here he married Miss Bess Gibson and later the family returned to Hudson, Wisconsin.

During his boyhood, Dr. Banks broke prairie sod, speared fish by torchlight at Fish Lake, and raced his horse at the Windom fair. He was a member of the Windom Drum and Bugle Corps of the '80's. With his brother, John, he hunted ducks with a "zulu" musket, the one sighting the gun while the other struck the firing pin. He heard his mother take part in contests and debates in the original opera house. He recalled one Christmas eve when the family set out with the oxen in a blizzard for a program at Bingham Lake and drove for two hours (a distance of two miles). When the oxen stopped on top of a haystack beside their own barn, they unyoked and had their "doin's" at home. He envied his father's experience in 1869 of seeing elk at Swan Lake.

A few days after the James Brothers' bank robbery at Northfield, in September, 1876, his older brother, John, was fishing at the north end of Bingham Lake, when he saw two strangers riding west, north of the lake, keeping away from the beaten trail and farm buildings. Later when the family learned of the robbery, they believed the two strange riders were members of the James gang, crossing Cottonwood County toward the Missouri valley. (Jesse and Frank James eluded capture.)

Dr. John H. Tilford encouraged William H. Banks to study medicine and took him on calls to patients.

Dr. J. F. Scott (now retired at Yakima), who succeeded Dr. Tilford later in the '90's, was the family's doctor. In 1922 he attended William Banks, Sr., at Yakima during his last illness, and cared for Dr. Banks in 1946.

To his own knowledge, Dr. Banks was the first child born in the county to become a physician.

Dr. and Mrs. Banks returned to Windom many times in the past twenty-five years for visits at the home of the Edward McCauley family, renewing old friendships and studying the geography and history of the region. As one more native son of Cottonwood County, he never forgot his Minnesota heritage.

Thomas A. Beach, who is said to have registered in Minnesota as a physician in 1887, was in Windom, Cottonwood County, in 1893.

Theodore Beck, in Windom in 1896, left Minnesota in that year for Ohio, it is believed. Research has not disclosed that he was licensed in Minnesota. A physician of this name was in Pleasant Hill, Ohio, in 1896; in Dayton, Ohio, in 1918.

Le Roy R. Brown (1855-1932) for one year of his forty-six years as a physician in Minnesota practiced in Windom, Cottonwood County, and for one year in Heron Lake, Jackson County.

Born on February 25, 1885, at Mankin, Michigan, Le Roy R. Brown was a son of Reuben J. Brown and Betsy Ann Kingsley Brown, both of whom were descended from veterans of the American Revolution. He was graduated in 1878 from the state normal school of Michigan in Ypsilanti, and thereafter for three years taught school in California. In 1881 he began to "read medicine," as was the custom of the period, and to assist in practice, with Dr. Brekke, of Ann Arbor, Michigan, and in 1882 he matriculated in the medicial department of the University of Michigan for a course of three years. On graduation, in 1885, with a degree of doctor of medicine, he began medical practice in Saint Paul, Minnesota; he was licensed as a physician in Minnesota on October 6, 1886, receiving certificate No. 1276 (R).

In 1887 Le Roy R. Brown was married to Mina Allen at Ann Arbor, Michigan. To this marriage were born three sons and three daughters. Mina Allen Brown died on May 7, 1907.

In 1896 Dr. Brown left Saint Paul for Windom, where he practiced about one year. For the following year he was in Heron Lake. In 1898, on returning to Saint Paul, he served as a medical fellow at the City and County Hospital. For a number of years he was associated with Dr. Schadle in the nose and throat work at the Saint Paul Free Dispensary, and later was in charge of the department. In 1915 he was appointed to the staff of police surgeons of Saint Paul. On his retirement in March, 1928, he estimated that in his years of service he had answered approximately 15,000 emergency ambulance calls. After his retirement he engaged in private practice, with offices in his home.

Dr. Le Roy R. Brown died on November 22, 1932, at the Ancker Hospital, Saint Paul, from cerebral hemorrhage, after an illness of three months. He was survived by two daughters, Mrs. Ralph E. Brewer and Miss Lucia Brown, both of Saint Paul, and a son, John R. Brown, of Kalkaska, Michigan.

Dr. Brown was a member of the Presbyterian Church and of fraternal organizations, among them the Masonic Lodge and the Independent Order of Odd Fellows, in both of which he held office at various times. His funeral was conducted at the Masonic Temple, Saint Paul, under the auspices of the Scottish Rite Masons.

William Thompson De Coster (1874-1945) was for forty-eight years a homeopathic physician in Minnesota, for two years (1899-18901) in Windom, Cottonwood County.

Born at Kingston, Meeker County, Minnesota, on August 25, 1874, he was a son of pioneer settlers of the state, Granville Foster De Coster and Mary A. Hall De Coster, both of whom were natives of Maine. Granville F. De Coster was first a farmer in Meeker County, next was in Watonwan County six years, and was then in Jarvis County. After 1901 he made his home in Winter Haven, Florida, where he died on May 7, 1923; Mrs. G. F. De Coster died in March, 1931.

William T. De Coster received his early academic education in the schools of Saint Paul. In 1897 he was graduated with the degree of doctor of medicine from the University of Minnesota College of Homeopathic Medicine and Surgery; he was licensed in Minnesota in that year, and thereafter practiced his profession continuously. For about two years after gradu-

ation he was in South Saint Paul, where in addition to conducting a private practice he was a contract surgeon for the Swift Packing Company. In February, 1897, he settled in Windom, Cottonwood County, where he practiced for two years. Early in 1901 he joined Dr. Walker in operating a hospital at Worthington; later, the two physicians established a hospital at Windom and in 1910 another at St. James, and until 1914 conducted the three institutions. Dr. De Coster then had a hospital in Madelia for two years. In 1915 he settled in Mankato, where he opened his private hospital. It is said that in this period he had a hospital in Rochester also.

Dr. De Coster was a public-spirited man, an independent thinker in politics, and a member of numerous fraternal organizations and of the Mankato Golf Club. He was deeply interested in the history and beauty of Minnesota, and his favorite hobby was visiting interesting localities in all sections of the state. He died in Mankato from coronary thrombosis on March 26, 1945. He was unmarried.

Noah Diamantenberg (1864-1932) was born Noa Dymenberg at Czernowitz, Austria, on March 15, 1864. When he came to America is not known. He was graduated from the Saint Paul College of Medicine with the degree of doctor of medicine in 1866 and was licensed as a physician in Minnesota on March 30 of that year, receiving certificate No. 1174 (R). He was for a time, in 1886, in Cottonwood County. Records of the American Medical Association disclose that he was licensed in Iowa in 1888, in Colorado in 1889, and in Illinois, in 1890. He was a resident of Minturn, Colorado, and was a member of the Colorado State Medical Society. His death occurred at Minturn on December 24, 1932, when he was struck by a train.

Charles A. Greene (1845-1910) was born in Rhode Island. He was graduated from the medical department of the University of Buffalo (New York) in 1873 and for two years thereafter practiced medicine in New York State. In 1875 he came to eastern Minnesota, where he engaged in practice some three years. The *Official Register of Physicians* of Minnesota for 1883-1890 states that he was licensed in the state on December 31, 1883; he held certificate No. 664 (R).

In 1887 Dr. Greene settled in Windom, Cottonwood County, where for twenty-three years he was a valued member of the community and an honored physician. Skilled in medicine and surgery, kindly and full of fun, courageous in the face of hazards, he never refused a call for his help, no matter how severe the weather or impassable the roads.

Dr. Greene was an active Mason, and was a member of the Grand Army of the Republic, a veteran of the Civil War, having served in Company A, Thirteenth Wisconsin Volunteers Regiment of Infantry from 1861 to 1866. When he died in Windom on November 10, 1910, he was survived by his wife and his daughter, Nellie, both of Windom, and by two brothers, John E. Greene, a lawyer in Minot, North Dakota, and Edward Greene, a professor in Washington, D. C.

Horace E. Harmon (1873-1913) was for twelve years a respected physician of Jeffers, Cottonwood County.

The following notes are based on an obituary that appeared in the *Jeffers Review* of January 30, 1913:

Horace E. Harmon was born at Faribault, Minnesota, on July 27, 1873. In 1879 he moved with his parents to South Dakota; in 1893 he was graduated from the South Dakota State College at Brookings. After four years of study of medicine at the University of Minnesota, he practiced medicine at Bryant, South Dakota, for one year. He next took a year's postgraduate work (1899) in a Minneapolis hospital. In 1900 Dr. Harmon settled in Jeffers; his residence was broken only by an absence of six months that year to take the degree of doctor of medicine at the University of Iowa, in Iowa City.

In October, 1902, Horace E. Harmon was married to Cora B. Potter. Mrs. Harmon died on April 23, 1908. Dr. Harmon was married on December 27, 1910, to Erna Luck. The only child of the first marriage, Lyle, died on March 24, 1912; the only child of the second marriage, Victor Edwin, died on September 10, 1912.

When Dr. Harmon died at Jeffers on January 26, 1913, after a week's illness from pneumonia, he was survived by his wife; his parents, Mr. and Mrs. T. Harmon, of De Smet, South Dakota; two brothers, Lyle, of De Smet, and Timothy, of Sherburn, Minnesota; and two sisters, Mrs. Michael Kelly and Mrs. Kittie Sturgeon, both of Dickinson, North Dakota.

His funeral services were held at Jeffers in the presence of hundreds who esteemed him; burial was at Windom. The *Jeffers Review* said: "During Dr. Harmon's twelve years of practicing medicine at Jeffers, he has made many friends throughout the entire county. No night was too stormy, no roads were too bad for him to make a call and administer to the sick or wounded. . . . He was a good doctor. . . . Dr. A. J. Moe of Heron Lake Hospital says: 'He was an ideal practitioner; it seems he was a natural born physician, and he had a fine success.' He was a kind and freehearted man, always standing for correctness and principle. He was a faithful friend to all, and we regret our inability to compose a better tribute to his memory."

Johannes K. Moen (1867-1929) was born in Telemark, Norway, on March 3, 1867. He immigrated to the United States at the age of eighteen years and settled in Red Wing, Minnesota, where he attended the Seminary. He later enrolled in the medical department of the University of Minnesota, from which he was graduated in 1893; he was licensed in the state that year.

After his graduation Dr. Moen set up practice in Windom, Minnesota, where he remained until 1908. He was coroner and health officer in Windom for several years. About this time he suffered the loss of his library and office equipment in a large fire.

Dr. Moen purchased his first automobile, an Oldsmobile, in 1901. It was a doubtful blessing, because he experienced much trouble making his calls in it, owing to bad roads; most of the time when he used his car in the country, he had to get farmers to pull him to town with horses. During the winter of 1899, driving his team, he had some especially bad trips on professional calls that he made to Westbrook, thirty miles away, and to Storden, twenty miles. Because of blizzards, it was not unusual in that period for him to be away from home two or three days at a time.

In 1908 Dr. Moen spent some months in Europe for postgraduate study, and on his return in 1909 he began his long medical practice in Minneapolis. For several years he was head physician of the Scandinavian-American Fraternity in Minneapolis. He was a staunch Democrat, a Mason, and an active member of the Sons of Norway. He had literary talent in both prose and poetry, most of which he wrote in Norwegian. Among his many interests and hobbies were fishing, which he particularly enjoyed, and botany; he had an interesting garden of medicinal plants.

Dr. Moen died in Minneapolis in 1929. Surviving in 1948 were his wife, in Minneapolis, one daughter and two sons. One of the sons, Dr. Johannes K. Moen, was in medical practice in Minneapolis.

Joseph Boardman Noble (1859-1947), a graduate of Rush Medical College, Chicago, in 1886, began practice in Windom, Cottonwood County, Minnesota,

the same year. He was licensed in the state, as of Tower, on May 3, 1886, receiving certificate No. 1185(R). After two years in Cottonwood County Dr. Noble removed, or perhaps returned, to Tower, where he remained until about 1900; in this period he was owner of a hospital in Tower and was a member of the St. Louis County Medical Society.

From 1900 until his death at the age of eighty-five years, Dr. Noble was established in Waukesha, Wisconsin. There is record that he was a member and past president of the Waukesha Medical Society and member of the Wisconsin State Medical Society. He was appointed city physician of Waukesha in 1902, was for many years medical examiner for several large national insurance companies, physician to the Wisconsin Industrial School for Boys, for twenty-five years district surgeon to the Chicago and Northwestern Railway Company, and was on the staff of the Waukesha Memorial Hospital. Active in local civic affairs, he served as member of the library board and as alderman.

Dr. Noble died at the Waukesha Memorial Hospital on May 5, 1944, from cerebral arteriosclerosis.

Charles Wilbur (sometimes spelled **Wilbor**) **Ray,** who was born in 1856, was a graduate of the Bennett College of Eclectic Medicine and Surgery, of Chicago, in 1885. On May 26, 1887, then in St. Claire, he received Minnesota state license No. 1414 (E). In the next twenty-two years he practiced medicine in various localities in the state, in the following order: St. Claire, Blue Earth County; Owatonna, Steele County; Canton, Fillmore County; and Nicollet, Nicollet County. In 1900, after a period of study in the East, he moved with his family to California. It is said that he was again in Nicollet for several years, about 1907-1909. He returned to California, where he died in 1912 in Los Angeles.

A fuller account of Dr. Ray's life appeared in 1947 in *Notes on the History of Medicine in Fillmore County Prior to 1900* (Guthrey), in MINNESOTA MEDICINE.

James Fred Scott, born in 1873, was graduated in medicine from McGill University, Montreal, in 1899, and in that year began the practice of medicine in Windom, Minnesota. In 1900, Dr. Scott was in Mankato. In 1905, a resident of North Yakima, Washington, he was licensed in Washington. He was in practice in North Yakima as late as 1947.

Allen Smith, the first practicing physician of Cottonwood County, arrived in Windom from Ohio, as stated earlier, on October 10, 1871. Two years later he returned to Ohio, where he died not long after his return to the state.

(To be continued in the September issue)

President's Letter

WHY AN AUXILIARY?

During the recent war, more than ever before, we saw eloquent proof that a woman's auxiliary can be a truly social service group. It can, if fully utilized, be a powerful force for the advancement of the aims of the parent organization and for the benefit of society as a whole—plainly and simply, an instrument *for getting things done.*

We do not need to count the bandages that were rolled, the sandwiches and coffee, and home-like hospitality that were extended to our servicemen, the fund drives, the scrap drives, the conservation drives, and the hours of hard work that went into the hundreds of major and minor projects. No one can put a price on the value of the job that women's auxiliaries all over the country did toward the winning of the war—even to the extent of marching to the front and serving in the nursing corps and in the auxiliary units of the army and navy.

All of these valued services were performed in greater or lesser degree by members of our own medical auxiliary, but it behooves us to recognize that their peacetime service is no less significant and even more valuable to us in discharging our professional obligations. As individuals, we look upon our wives as helpful companions and valuable assets. The old quip that a wife is both a necessity and a luxury represents the two attitudes which we may take. We may regard our woman's organization as "just something to put up with—not much good, but harmless," or, if we are alert to its possibilities, we can delegate to it certain responsibilities for carrying out projects for which it is particularly well adapted and which in many cases we cannot undertake for ourselves.

We readily recognize the value of women as wives and mothers in the rôle of homemaker. But with their auxiliary group they are in a peculiarly advantageous position to strengthen our relationships with the layman and to interpret our ideals and aims to the public.

We should welcome this assistance; for surely certain aspects of our public relations are not to be slighted; we cannot afford to overlook the liaison value of our wives. There are instances where they can aid us immeasurably, where they can speak for us—where we cannot speak for ourselves—as in the field of public health education. They can, as a group, sponsor many worthwhile projects which have as their ultimate aim the spread of authentic health information, and they can conduct these activities without fear of criticism. The code of medical ethics does not forbid doctors' wives speaking in behalf of the advantages which adequate medical attention has over home remedies, self-medication and patent medicines.

It is only natural, furthermore, that the wife of a man who is respected in the community will also share some of that respect. It then follows that she should have a share in some of his community responsibilities. Among them would certainly be to inform and enlighten in matters of health.

Thus, in these times when the medical profession is engaged in a serious fight to preserve freedom of enterprise for itself and the world, we welcome the thoughtful, conscientious effort of the Woman's Auxiliary in our behalf. A bright future for service to humanity is before this group, and we are proud that they are willing to accept this challenge.

President, Minnesota State Medical Association

CORRELATION OF PRIVATE AND TAX-SUPPORTED HEALTH ORGANIZATIONS

THE interest of the public in health matters is manifest in its generous support of the numerous agencies devoted to the problems of tuberculosis, infantile paralysis, heart disease, cancer, rheumatic fever, high blood pressure, crippled children and adults, et cetera. We can foresee the need of a better co-ordination between the activities of these voluntary organizations and those supported by public expenditure of tax funds, notably by the United States Public Health Service.

Antituberculosis activities, supported by the yearly purchase of Christmas seals, were the first in the field, and the outstanding reduction in tuberculosis is partly a result of the publicity regarding tuberculosis prevention and health matters which have been this organization's main function and in large measure the result of the establishment of sanatoria at public expense. There has been no overlapping of activities in this field.

The response to the appeal for funds for research in poliomyelitis and the relief of its victims has furnished millions of dollars yearly for the National Foundation for Infantile Paralysis. The predilection of the disease for children has provided an emotional appeal which has resulted in the raising of funds out of proportion to the number of its victims. The addition of a second agency in the same field, the Kenny Institute, has increased this disproportion. We read in the Washington Report on the Medical Sciences of June 14, 1948, that a catch-all health bill (H.R. 6732) failed to pass in the last days of Congress, only because a committee report which was supposed to accompany the bill could not be found when the bill was called upon the floor of the House. The bill would have given the Surgeon General of the Public Health Service broad powers to establish research institutions for poliomyelitis and such other diseases as he might deem necessary, and furthermore to give financial assistance to existing poliomyelitis agencies.

The high toll of heart disease has aroused growing concern in various quarters. The Life Insurance Medical Research Fund, established in December, 1945, by the life insurance companies, spent a million and a quarter dollars in support of some eighty-nine research programs and fellowships in 1946 and 1947. The American Foundation for High Blood Pressure, with headquarters in Cleveland, has just announced the allocation of $75,000 for research in hypertension, arteriosclerosis, and associated conditions. The Variety Club, with headquarters in Minneapolis, has been most generous in its contributions to the study and care of rheumatic and other heart diseases. In June, Congress passed the National Heart Act aimed to curb cardiovascular disease by stimulating research, professional training and public control measures, which promises to lead up to a program which will be the largest ever undertaken by the U. S. Public Health Service. Approximately 3 million dollars have been appropriated to get the campaign started and to establish a National Heart Institute to be housed in the 40 million dollar clinical research center to be erected at Bethesda, Maryland. It is expected that eventually some $15,500,000 will be spent on the program annually. The bill was backed by the National Heart Committee and the American Heart Association. The American Heart Association and its affiliates now plan to conduct an annual campaign to raise funds from the public to be used partly for research and partly for public and professional education and improvement of facilities for diagnosis and treatment of heart disease. While such uses do not duplicate those of the Life Insurance Medical Research Fund, the question arises as to whether the new USPHS activities will not prove to be a duplication.

Cancer also presents a serious medical problem. The American Cancer Society has been conducting drives each year for the raising of funds to combat this disease and in its last campaign raised $12,111,000, some $284,000 having been raised in Minnesota. Last year Congress appropriated 14 million dollars for cancer work, $2,303,000

having been allocated for the construction of clinical research and laboratory facilities. The House included in this bill an appropriation of 8 million more to provide facilities and establish training projects relating to cancer. Research in cancer is to be included in the 40 million dollar combined hospital and research building being erected in Bethesda, Maryland. Much of this money will be spent by the National Cancer Institute, part by the U. S. Public Health Service in cancer research and grants-in-aid to other institutions and to individuals for cancer research.

Also passed by the last Congress was a bill providing for 2 million dollars for a National Institute of Dental Research at Bethesda, Maryland.

Each year the National Society for Crippled Children and Adults, Inc., puts on a campaign for raising funds for this worthy object.

The Medical Economics section in this issue of Minnesota Medicine contains information regarding a bill to establish a National Science Foundation to initiate and support basic science research, one of the four divisions of which would be medical research. That this bill had considerable backing is attested by the fact that it was passed by Congress but vetoed by the President. Will this bill be passed by the next Congress? If so, will it not duplicate the research provisions of the National Heart Act mentioned above?

The Federal government is apparently entering the medical research field in a big way by subsidizing such research in the medical schools and by establishing its own medical research institutions. The medical school of the University of Minnesota is one of seven medical schools in the country which receive over a half million dollars yearly in research and educational grants from the various divisions of the U. S. Public Health Service. Perhaps, with the present dearth of contributions for medical research from private sources, such federal assistance is necessary. It is favored by certain members of the profession.

It seems to be a general belief that if enough millions of dollars are available for medical research, the problems will be solved. History does not confirm this belief. The outstanding medical discoveries so far have not been dependent on millions of dollars but rather on a comparatively few medical research workers. Scientists with the qualities essential for research are few and far between, and funds can be easily dissipated in the name of research, if their expenditure is not judiciously supervised.

The status of medical research presents a confused picture and raises several questions. Are the funds raised through voluntary contributions to the various national organizations sufficient for carrying on adequate research? If not, is governmental subsidy necessary? If so, should participation by the government be limited to subsidy of existing research institutes, or should the government also carry on its own research programs? If the government is going to appropriate millions of the taxpayers' money for medical research, should the public be asked to contribute additional millions for the same purpose?

The demands being made on individuals and corporations for contributions, not only to societies involving medical activities but also to the great array of other charitable and philanthropic activities, have become well nigh unbearable. Individuals are not in a position to evaluate the many demands made for contributions. The various Community Chests have helped to solve the local charity problem but are not of assistance when it comes to the many organizations of national scope.

According to an editorial in the *New England Medical Journal* of June 24, 1948, a study is on foot to analyze the 88 million dollars spent in the vicinity of Boston in 1946 by tax-supported and voluntary agencies. Presumably this study will result in a clarification of the subject. Similar studies on a state-wide and national basis would be of great value.

RED CROSS BLOOD BANKS

At the close of World War II, a surplus of some 2 million pints of blood plasma was returned to the Red Cross. This was distributed to the various State Departments of Health and redistributed gratis to the various hospitals. The supply has been about exhausted.

The use of blood and its derivatives has greatly increased in recent years. Their value is by no means restricted to war needs, although in case of an atomic war, they will be invaluable. Their cost to patients and the difficulty in keeping blood banks supplied have proven serious problems in the past. The Red Cross, therefore, seriously considered the advisability of continuing its blood program following the war, and after

numerous regional meetings of Red Cross representatives and almost unanimous agreement, the Board of Governors of the American Red Cross gave its approval to the undertaking. Regional blood banks will be established all over the country providing the approval and co-operation of the local medical societies are obtained. Blood centers will collect the blood from volunteer donors and will finance the costs from Red Cross funds. It is anticipated that the project will cost from 3 to 5 million dollars the first year and probably more in succeeding years. Blood and its derivatives will be furnished without charge to all hospitals—civilian and governmental—for all patients irrespective of their financial status. A reasonable charge for administration will be allowed hospitals and physicians.

Already several Red Cross blood centers are in operation. Saint Paul is to have one of the first ten. With the approval and co-operation of the Ramsey County Medical Society, plans are under way to establish a center at 91 East Kellogg Boulevard near the present Red Cross headquarters. It is expected that operations will begin about November 1, 1948, for supplying hospitals in Ramsey County and its environs.

The Red Cross blood bank program requires the wholehearted support of the public and medical profession, if it is to be successful. In keeping with all other activities of the American Red Cross, the program is a philanthropic one. The public will be asked to donate blood in peacetime, as it did during the war, so that blood may be obtainable in sufficient quantities for the saving of lives. The problem of the great cost of blood transfusions is to be eliminated.

The program has received the approval of the AMA with the understanding that the establishment of blood banks shall be with the approval of the local medical society, and any difference of opinion as to the establishment or operation of a blood bank shall be arbitrated at state levels by joint committees from the state medical society and the American Red Cross. On a national level, the House of Delegates of the AMA, at its meeting in January, 1948, appointed a special committee to work with the physicians comprising the Advisory Committee of the American Red Cross. The two committees will continue to work together in this philanthropic venture.

As the undertaking is a long-term proposition and will require several years to reach full operation, it is urged that present blood banks other than Red Cross continue to function, with the idea that many may be taken over eventually by the Red Cross.

AMERICAN HOSPITALS

Almost 18 million Americans were admitted into the 6,173 hospitals of the United States in 1947, according to the 1948 American Hospital Directory compiled and published by the American Hospital Association. This represents an average of one of every eight Americans receiving hospital care.

Approximately 16 million patients, two million more than in 1946, were admitted to general hospitals during the year, the Directory reports. In addition, 40 million hospital visits were made by outpatients, those needing special tests or treatments without bed care.

The average cost of caring for a patient for one day in a general hospital rose from $9.39 to $11.09 in the year 1946-1947, according to the Directory. Yet the average income from patients was $9.71, leaving a daily deficit of $1.38 per patient to be made up through voluntary contributions and gifts from the public.

Part of the $2,354,344,000 expended by hospitals in 1947 was for the salaries of the 79 fulltime employes serving every 100 patients in all types of hospitals, the Directory states. General hospitals had approximately 151 employes for every 100 patients to maintain prevailing high standards of patient care. Hospitals spent about 400 million dollars more in 1947 than in 1946, because of higher wages, higher prices, and expanded services.

The average patient going to a general hospital in 1947 stayed for only eight days, as compared with 9.1 days in 1946, the figures show. This reflects the spreading practice of entering hospitals in earlier stages of illness, possible for increasing numbers of people through Blue Cross and other prepayment plans, as well as wider recognition of the value of hospitals, improved treatment methods, and early ambulation.

Hospitals in 1947 had total assets of approximately six billion dollars, which is more than $42 for every man, woman and child in the United States. Of that amount, general hospitals' plant valuation represents almost three and a half billion dollars, an average of $7,500 per bed.

"Ten years ago, in 1937, 9,221,517 patients were admitted to hospitals," George Bugbee, executive director of the American Hospital Association, reported. "During this ten-year span, hospital admissions have increased almost 100 per cent.

"The facts revealed by the Association's survey dramatically illustrate the increased recognition of the place of hospitals in the nation's health and welfare."

A GUIDE FOR PUBLIC HEALTH NURSING AGENCIES SEEKING TO ESTABLISH POLICIES AND STANDING ORDERS

(June, 1948, Revision—Recommended by the Committee on Public Health Nursing and approved by the House of Delegates, Minnesota State Medical Association)

Local public health nursing practices must be consistent with the medical practices of the community. In recognition of this fact and in the interests of the public welfare, the Minnesota State Medical Association, the Minnesota State Organization for Public Health Nursing and the Division of Public Health Nursing of the Minnesota Department of Health have jointly agreed upon certain minimum policies and standing instructions involving nursing procedures. They are herewith submitted as a basis for guidance of organized public health nursing agencies. It is intended that these minimum policies and instructions will be found sufficiently flexible to meet various local needs.

Agency Policies

1. An agency employing public health nurses should have its basic program and contemplated changes approved by the physicians in the community.

2. The nurse emphasizes the importance of medical care, but she does not recommend the selection of any one individual physician. Except as provided for in policy 10, she gives bedside nursing care and health instruction only under the direction of a licensed physician. Public health nurses working under the direction of local physicians may give and read various diagnostic tests provided approval has been given by the physicians of the community. Likewise, public health nurses may administer immunizing agents, provided they have received specific written authorization or direction for such procedure from the physicians of the community.

3. In special cases of economic need the public health nurses, after consultation and in co-operation with the family physician, may refer patients to the health facilities provided by public and private agencies.

4. The establishment of clinics or other health activities which involve medical service shall be undertaken only upon the approval of the County or District Medical Society, or by the physicians in the community.

5. Records of nursing care should be kept on file by the nurse. The nurse should make a written report to the physician or agency whose patient she has contacted. Such report may be given to the patient to take to the physician, or may be delivered directly to the physician.

6. Every public health nurse should understand and support the state and local health laws and regulations and keep in direct contact with the local and state health departments.

7. Every nurse engaged in public health nursing should become approved by the Committee on Certification, for which provision has been made in Section 145.10, Minnesota State Health Laws and Regulations.

8. It is suggested that all public health nurses, at the time of employment and periodically as requested by the employing agency or the State Board of Health, present a satisfactory personal health record which should include recent smallpox vaccination, evidence of immunity to diphtheria, and freedom from active tuberculosis, as determined by tuberculin tests and/or x-ray pictures of the chest, and other procedures as indicated.

9. Upon consent of the family physician, public health nursing agencies may assign simple nursing duties to persons who have had limited training for such work. Such persons shall receive instruction and supervision for their assignment from the public health nursing agency.

10. The training of public health nurses is carried out exclusively as a collateral service to the philosophies and practices of physicians and surgeons. Therefore, except under highly unusual circumstances, public health nurses should not be expected to answer to the directions of persons other than licensed physicians and surgeons. Provided, however, that public health nurses may carry out nursing functions under the direction of other licensed health practitioners insofar as the practices of the latter, in medical and surgical fields, are within the limits of their licensure, and insofar as such orders may be compatible with the training and experience of public health nurses to perform.

Standing Instructions for Care or Service of Patients

The content of health education to be taught by the public health nurse in the home, the school or the health center, and the quality and quantity of nursing care for sick persons, either under or pending medical direction, are matters of joint concern to the physician and nurse. The following recommendations are offered to nursing agencies as a guide for the establishment of standing orders to the nurse in her administration of nursing care, treatment and medication in those emergencies where no physician is in attendance or when orders have not been left by the attending physician or when the nurse is unable to reach the physician for orders. Before adoption by an agency, all such standing orders should be approved by local physicians.

Emergencies and Accidents—All nurses are expected to be familiar with the techniques adopted by the American Red Cross for first aid treatment and injuries, and in caring for such conditions she will limit herself to these accepted procedures. In the event of a severe accident, immediate medical care should be secured by calling the nearest physician or hospital if it is not possible to locate the family physician; and if the patient is a minor, the nurse should communicate with the parent or guardian immediately.

Communicable Disease Control—The control of communicable diseases is the responsibility, not only of the public health nurse and the official agency, but is also the concern of the medical profession and general populace. If communicable disease is suspected, the nurse should explain to the family the elementary principles of isolation, concurrent and terminal disinfection and such other measures which will aid in preventing the spread of dis-

ease. (See "Home Isolation Procedures," Manual for Public Health Nurses, Minnesota Department of Health.)

If the patient is attending school, the school official should be notified in writing in order that contacts of the patient may be properly observed. The health officers of the sanitary districts in which the school is located and in which the child resides should be notified of the occurrence of suspected communicable disease, as provided by Regulation 318 of the Minnesota State Health Laws and Regulations. The nurse is expected to make the patient as comfortable as possible and to isolate him from all other persons. Any of the following symptoms shall be considered sufficient reason for such isolation:

Fever 100° or more	Sore throat
Coryza	Vomiting
Rash	Inflamed eyelids
Running ears	Pediculosis
Skin lesions suggesting scabies or impetigo	

In aiding physicians in the control of preventable diseases, public health nurses are expected to co-operate with the local health officer and to follow the Regulations of the State Board of Health.

The nurse should teach families that immunizations are best done before the end of the first year of life, and thereafter repeated at the discretion of the physician. Group immunization programs should be conducted under the auspices or with the approval of a local medical society, which may secure available biologics from the Minnesota Department of Health. The nurse's contribution to such programs consists of preliminary education of the community, making the necessary arrangements for carrying through the programs, assisting the physicians when the immunizations are being performed, summarizing reports, and keeping local records of immunization.

Tuberculosis Control—Infectious and potentially infectious cases (active or with tubercle bacilli in sputum) preferably should be isolated at a sanatorium immediately following establishment of the diagnosis and procurement of such recommendation from the attending physician or health officer. Such cases, while awaiting admission to the sanatorium, should be completely isolated at home. (See communicable disease isolation procedure in Public Health Nursing Manual supplied by the Minnesota Department of Health.) Special attention should be given to adequate terminal disinfection after the patient has left the household. Hospitalization should also be advised for other forms of tuberculosis on the approval of physician. Medical examinations, including tuberculin tests and x-ray pictures, should be urged for all members of the family and other close contacts of tuberculosis cases. Where local medical society approval is had, the Tuberculosis Control Officer of the State Board of Health can arrange for mass x-ray surveys of a community.

Syphilis and Gonorrhea Control—As problems in relation to syphilis and gonorrhea are encountered or brought to the attention of public health nurses, all available information regarding these problems should be referred to the Section of Preventable Diseases, Minnesota Department of Health, for consultation and advice regarding future responsibility of the nurse. When cases are known to be under medical care, problems relating to them should first be discussed with the attending physician.

Public health nurses should always bear in mind that information relating to venereal disease should be kept confidential. (See Regulation 2510, Minnesota State Health Laws and Regulations.)

Health of Mothers—The public health nurse's work with mothers and infants is an important part of public health service. She should secure standing orders from individual physicians for treatment and nursing procedure to be carried out for these individuals.

In working with expectant mothers the aims should be to bring the women under early and continuous medical care; to teach the elements of prenatal hygiene; and to carry out nursing care or treatments ordered by the physician. Specific help which public health nurses may give to mothers includes: help arrange for delivery care for the mother and immediate care for the new baby; demonstrate the preparation of sterile supplies when a home delivery is planned; if possible, help arrange to have a registered nurse present during delivery when home confinement is anticipated. They give bed baths and perineal cleansing (demonstrate to attendant). They give treatments ordered by the physician (demonstrate to attendant). The nurses emphasize the value of rest and other aspects of hygiene during the involution period and the value of the postpartum medical checkup. In the event of postpartum hemorrhage, nurses give emergency care—send for the physician, apply gentle massage to the uterus, keep the patient quiet and warm, and carry out the measures recommended for the treatment of shock.

A most important phase of the maternal care is instruction in the value of breast feeding for the baby with its attendant physical and emotional preparation of the mother for a successful breast feeding experience. Infant feeding schedules shall be determined by the attending physician.

Health of Infants and Young Children—A most important phase of public health nursing is instruction in care, feeding and immunization of infants. Every effort should be made to contact the mother of the new infant within forty-eight hours after birth in the home or baby's return from the hospital.

The definite decline in breast feeding challenges the public health nurse to encourage mothers to nurse their infants. The nurse must be familiar with the various techniques involved. She must ascertain from the physician that there are no contra-indications.

The prophylactic protection of the baby's eyes and registration of birth as required by state law is the nurse's responsibility when there is no doctor in attendance.

The birth of a premature infant is an emergency in which the public health nurse must be prepared to function under the direction of the attending physician. A definite prearranged program of co-operation between the physician and the public health nursing service will enhance this program. The nurse's contribution of aid and instruction in maintaining body temperature, feeding

techniques, isolation and other nursing care can be invaluable.

The nurse should concern herself with guiding parents of preschool children in habit training, adequate nutrition, good hygiene and immunizations. Close co-operation should prevail between nurses and organizations such as the Congress of Parents and Teachers, American Legion Auxiliaries and others particularly interested in promoting such special health programs as health examinations, child health conferences, dental health projects, etc., for the preschool child.

Health of School Children—The public health nurse in school health work is usually under the immediate direction of the school administrator. In addition, the Nursing Advisory Committee or the School Health Council, each with medical, dental and lay representation, helps guide the service. The nurse consults with parents on problems of child health and environment and guides parents to other sources of aid which may be needed. The nurse co-operates with the school staff, parents, physicians and dentists in arranging for and conducting health examinations in such a manner that the examinations become an educational experience for all participants.

The school nurse aids in the control of communicable disease by helping parents and teachers recognize conditions for which the child should be isolated. Regulation 318 of the State Board of Health Laws and Regulations provides for reporting children who are ill to the school physician for medical examination. On the other hand, where there is no school physician "it shall be the duty of the teacher or head of the school to exclude from school all pupils, who, in his opinion, show signs of a communicable disease." A nurse may perform these duties when so directed by the school physician or the health officer.

Morbidity—Nursing service rendered by public health nurses to patients ill from any cause is included under this category. The public health nurse must make every effort to keep the physician informed of services she has given to the patient and progress she has observed. Except in services where the policies include bedside nursing, the public health nurse cannot be expected to give continuous bedside care to an individual: first, because of the need for equitable distribution of all phases of a generalized service to all sections of the community; and second, because of the possibility of disrupting the balance of a generalized program. However, where medical and hospital personnel are reduced, the public health nurse working under medical direction may render care to the sick in their homes for demonstration and teaching purposes, thus giving vital assistance to physicians as well as improving the care of the patient.

Whenever the public health nursing agency has assigned nursing duties to an auxiliary worker, a public health nurse will visit the case frequently enough to know that treatment and care are given as ordered by the physician.

It is generally accepted that the nurse's first morbidity visit may be made without there being or before there is a physician in attendance. Standing orders should include definite regulations regarding subsequent visits as well as policies to guide the nurse on the first visit. At the first call every effort should be made to have the patient contact the physician of his choice. The physician will then give orders to the nurse for subsequent visits. Written or telephoned reports to the physician are desirable, both for the first and subsequent visits. Ordinarily, repeat home visits, when there is no physician in attendance, are made chiefly to urge medical supervision and to secure diagnostic information to be reported to the attending physician or health officer.

Crippled Children's Services—The State Service for Crippled Children requires full co-operation of all interested local agencies to fulfill its functions. The prevention and correction of physical handicaps due to bodily defects needs supervision over long periods of time. The nurse works with the individual physicians in the care and supervision of these cases.

Due to her close contact with the patient, the public health nurse may discover deviations from the normal—not only in the infant, but also in the preschool and school child. She helps parents make precise and concrete plans for the regular and continuing medical care of the crippled child.

Records of local orthopedic and cardiac cases and those of other physical defects should be as complete as possible and checked frequently with the state field representative of Crippled Children Services. The nurse's duties in the individual case lie in the education of the family in the patient's care, the demonstration of and instruction in home nursing, the general health supervision of the afflicted child, and the supervision of therapeutic exercises recommended by the physician in charge. The nurse will aid the rehabilitation of the patient in every way.

PRACTICE OF MEDICINE IN RAMSEY COUNTY

(Continued from Page 866)

to exclude or curtail the activities of the general practitioner. However, it is the duty of all hospital staffs who are true to their profession to establish regulations necessary to prolong life, to reduce mortality and morbidity. It is to this end that self-imposed rules are laid down by the staff which include more consultations, all for the benefit of the patient, the doctors, and the hospital.

In closing, I would say, be true to yourselves and your profession so that you will always be proud of your profession and your profession will be proud of you.[4]

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

CONGRESS PASSES RECORD NUMBER OF HEALTH BILLS

Public health, medical and hospital legislation, was enacted into law in record-breaking proportions during the second session of the Eightieth Congress just recently completed. Federal health insurance again failed to make the grade.

Bills adding new duties to the United States Public Health Service and rearranging certain of its administrative functions; measures applying to the Veterans Administration and certain other general proposals were written into the statute books.

A number of desirable pieces of legislation such as the National Science Foundation and federal subsidation of local public health units were left behind in committees of the House and Senate. That raises the question if there might be a possibility of action on them during the special session. However, according to a Presidential statement issued at the time of his calling of the session, other "must" legislation and more urgent matters such as civil rights, housing, wages and the possible repeal of the Taft-Hartley Labor Act, will occupy the lawmaker's time.

The first session in 1947 of the Eightieth Congress passed only a handful of medical and health bills compared to the tremendous output at the second session. The heated controversy over whether to federalize or not to federalize medical care raged during both sessions. Hearings on two opposing bills—S.545 and S.1320—filled nearly six volumes.

Heart Disease and Water Pollution Attacked

Private efforts as well as government activities to combat heart disease were given a substantial boost by the National Heart Act, one of the bills just passed. This Act provides research grants, fellowships, nationwide control programs and other projects much like those for attacking cancer, venereal disease and mental illness previously instituted.

A National Advisory Heart Council of heart disease experts together with laymen is established with no ceiling on appropriations. Also a National Heart Institute to be located at Bethesda, Maryland, is authorized.

The first comprehensive water pollution law in national history was passed by the Eightieth Congress. Administering the law becomes the responsibility of the Surgeon General of the Public Health Service and consists of helping states, industries and municipalities in planning and carrying out remedial programs.

The major problem in preventing water pollution is felt to be one of disposing of industrial wastes. Under the new law, funds are authorized for loans to construct municipal water treatment plants, investigations of existing preventive measures and construction of a Public Health Service laboratory at Cincinnati.

Dental Research Promoted

A bill to set up a National Institute of Dental Research and an advisory council similar to the heart group was also passed. It authorized $2,000,000 for the construction of an Institute to be located at Bethesda, to equip it and to provide grants-in-aid.

The Hospital Survey and Construction Act was liberalized by another measure. The Virgin Islands are now eligible, and states are granted additional time in which to enact legislation necessary before they can receive federal funds.

Two bills are aimed at improving health in the Philippine Islands. One bill authorizes training of a limited number of Filipinos in public health methods and administration in U. S. schools together with the establishment of public health training centers in the Philippines. Another sends financial aid to Filipino veterans of the Japanese resistance movement.

Several other measures were enacted which pertained to veterans. Research on various pros-

thetic and sensory appliances is authorized; intern training is established in VA hospitals whereas formerly there were only residencies; service-connected paraplegia cases are granted financial assistance to enable them to acquire or remodel dwellings suited to their needs; and several tropical diseases are added to the list of ailments for which service connection can be claimed in obtaining medical care at government expense.

U. S. Joins World Health Organization

United States membership in the World Health Organization was finally passed by both houses of Congress after a compromise had been reached which was well padded with safeguards and loopholes. The bill places a ceiling on this nation's share of expenses of WHO, and the stipulation is made that our membership will not commit the United States "to enact any specific legislation" regarding matters referred to in the WHO Constitution. The U. S. reserves its right to withdraw from WHO on a one-year notice.

Our representative on the WHO executive board will be a graduate of a recognized medical school who has spent not less than three years in active practice. He will be appointed by the President and confirmed by the Senate. The first meeting of the World Health Assembly took place at Geneva on June 24. The President sent three delegates: Drs. Thomas Parran, James R. Miller and Martha Eliot.

Several other miscellaneous measures relating to health were passed. The Food, Drug and Cosmetic Act was amended to make it a criminal offense to adulterate or misbrand drugs, foods, therapeutics or cosmetics even after interstate shipment has been completed and they are ready for retail sale. The federal government also is doubling its annual contribution to the Gorgas Memorial Laboratory in Panama, which is engaged mainly in tropical disease research.

Exposed x-ray film may now be imported free. No physically handicapped person may be discriminated against in connection with civil service appointments, transfers or promotions.

Science Foundation Dropped

Among the many important bills affecting medicine, adversely or favorably, which failed to get out of committee was S.2385 to establish a National Science Foundation. This is the second time attempts to establish the foundation have failed. Last year President Truman vetoed a similar measure.

Briefly, the National Science Foundation would initiate and support basic science research; would develop and encourage adherence to a national policy with regard to research and education in the sciences (including medical science); would appraise impact of research on industrial development and the general welfare; would enable persons with ability to receive scientific training through scholarships and graduate fellowships; and would correlate its program with that of individual and public research projects. Also it would foster interchange of scientific information among the scientists of this country and abroad.

The National Science Foundation would be an independent agency of the federal government with a director and 24 members appinted by the President. An executive committee of nine would implement the policies developed by the foundation. There were to have been four divisions—(1) medical research, (2) mathematical, physical and engineering sciences, (3) biological sicences and (4) scientific personnel and education, which would grant scholarships and graduate fellowships.

Fortuantely, S.140, a bill to create a Department of Health, Education and Security with its head a member of the President's cabinet also failed to get out of committee. The two opposing "health insurance" measures, S.1320 (the Wagner-Murray-Dingell Bill of 1948) and S.545, the Taft-Smith-Ball-Donnell Bill, were unable to get past the discussion stages.

COMMITTEE HOLDS LINE ON HEALTH INSURANCE

A thorough investigation of the pros and cons of compulsory national health insurance, which is to be continued by Congressional action, was undertaken by the subcommittee on health of the Committee on Labor and Public Welfare of the Senate. Thus the line was held on health insurance through one more Congressional term.

To this subcommittee were referred the various measures calling for national health plans; and under the leadership of Senator H. Alexander Smith, the group has employed every available means to get at the facts and obtain an impartial view of our national health status before giving the go-ahead signal to any remedial programs.

During the closing sessions of the Eightieth

Congress, Senator Smith submitted a detailed report of his subcommittee's activities. At that time his request that the work be allowed to continue was granted; a full report is to be made to the next Congress not later than March 15, 1949.

In its search for facts and opinions on health legislation, Senator Smith's group polled the governors of the 48 states and found that none of those answering the poll favored a federally administered medical care program. An impartial research agency, the Brookings Institution, was also asked for its opinion. This group brought in a report which was very damaging, to say the least, to the pro-nationalists' arguments; compulsory health insurance rated the Institution's unqualified veto.

The subcommittee considered no less than twenty-seven bills on proposed health legislation during the last session of Congress, it was revealed. Of these, the two comprehensive and most important proposals were, of course, S.1320 and S.545. These bills, which represent the two opposing sides of the national health controversy—one side insisting on federal control and the other upholding the rights of the individual states to set up their own programs—contain provisions which affect, overlap and duplicate the contents of most of the other bills considered by the committee. For that reason, the most of the subcommittee's time was taken up with considering them. Twenty-six days of hearings were held on S.545 and S.1320, with a number of government officials and heads of national groups being called in to testify.

Fundamental Issues Analyzed

In the report to Congress, Senator Smith analyzes the basic issues which must be considered in designing federal health measures. First and foremost, Senator Smith points out, there is the question as to whether a serious national health problem actually exists. This is debatable and involves consideration of the state of health of the population; the distribution of medical, hospital, dental and other health services and whether the majority of the population has access to such services.

Another important consideration is the fundamental question as to whether it is necessary for the federal government to expand its operations in the field of health. Available evidence suggests that wide-scale federal intervention, particularly in the field of medical care for individuals, may not be sound practice.

A third fundamental question is the methods or systems to be employed in providing medical and health services to individuals in the event of further expansion in this field, for example, the grant-in-aid system to assist states in developing their own health programs and the compulsory health insurance plan wherein the people are taxed to support a central health fund.

The fourth consideration that Senator Smith points out is that each piece of proposed health legislation should be considered in its proper relation to other pending matters, rather than individually. Moreover, health legislation should be considered with regard to other broad welfare programs of the government. The long-range effects of such proposals as compulsory health insurance and wide-scale grants-in-aid to states when their costs are added to the burdens of existing programs should be considered.

A vital question is that of selecting the proper administrative organization for dealing with health functions. At present, health programs are widely scattered throughout various departments with a sad lack of co-ordination. Last, but not least, Senator Smith concludes, there is the fact, often overlooked, that health simply does not exist in a vacuum. It is the result of an interplay of a vast number of factors. Providing for medical care alone will not meet other needs that exist nor insure good health for the nation. It is extremely doubtful that people can be legislated into good health.

With Senator Smith on the subcommittee on health are Senators Ball (Minnesota), Donnell (Montana), Murray (Montana) and Pepper (Florida).

ROLE OF COUNTY SOCIETY REAFFIRMED AT AMA MEETING

The County Medical Society—its part in medical organization and its responsibilities to its membership and the public—was discussed at the Grass Roots Conference of County Medical Society Officers, which was a prominent feature at the recent American Medical Association meeting in Chicago.

The AMA meeting this year was well attended. Total registration was 11,963 fellows. Doctors' wives, guests and exhibitors brought the total attendance to nearly 22,000. The County Offi-

cers' meeting which was held on the Sunday preceding the meeting proved popular and valuable.

At the meeting it was pointed out that the size and spread of the county societies' activities vary in accordance with the locality in which they are located. The problems of organizational responsibilities vary widely and are often complex. Interesting background information concerning the county medical society's relation to its respective state medical association as a component of the American Medical Association was presented.

Problems in programming were also discussed, and it was shown that here again each society has a different set of problems to meet, depending on the locality and facilities available—whether programs should be held once a month or once a week; whether well-known outside speakers should be brought in or the program should be prepared and presented by local society members.

Name "Organized Medicine" Deplored

It was suggested that the name "organized medicine" should be changed to "scientific medicine," a suggestion which might be used to great advantage from the standpoint of public relations.

Among the pressing problems present at the local level which need solving and which were discussed at the meeting were night calls, uniform fee schedules for indigents' care and county society participation in local activities. It was emphasized that no health agency should be overlooked or overemphasized by the county medical society. The topic of Community Chest and the place of the medical profession in the drive for funds was emphasized both from a community service angle and as a public relations gesture.

Health councils were stressed as projects in which the county medical society should not only participate, but could well afford to take the lead.

The major burden of public relations was placed squarely on the shoulders of the local organization as the basic unit of our medical structure. In his president's address, Dr. Edward L. Bortz emphasized the position of the county society by calling public relations the "field of human relations," which brings the problem right down to the individual physician.

As the basis for an active society, the great importance of carefully selecting and maintaining membership was discussed. Indoctrination courses on ethics for new members was recommended.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building
Saint Paul, Minnesota

Julian F. DuBois, M.D., Secretary

Health Food "Doctor" Pleads Guilty to Violation of Basic Science Law

Re State of Minnesota vs. "Dr." Lloyd C. Shanklin.

On July 14, 1948, Lloyd C. Shanklin, fifty-four years of age, with no permanent address, entered a plea of guilty in the district court of Hennepin County to an information charging him with the crime of practicing healing without a basic science certificate. Shanklin was sentenced by the Hon. Lars O. Rue to a term of one year in the Minneapolis workhouse. The sentence was stayed upon condition that Shanklin return the money he had received while giving so-called health lectures at the Andrews Hotel, Minneapolis, just prior to his arrest.

Shanklin was arrested July 9, 1948, by Inspector Bernath of the Minneapolis Police department following a report that Shanklin was to give a course of three health lectures at a reduced price of $15, the usual price being $75. As a special inducement, Shanklin was going to give $3 worth of vitamins and health food to each person attending his lecture course. Shanklin was arrested before he had much of a chance to proceed with his lecture course. Shanklin stated that he was born in Lynn County, Iowa, and that while he was not a high school graduate he claims to have studied many subjects including health, sex, foods, religion, et cetera. However, he had no diplomas and admitted that he was not licensed in any state to practice any form of healing.

Shanklin admitted that he had been arrested in New York City on two occasions for similar violations in 1942 and 1944. Shanklin claims to have been on a lecture tour in Ohio before coming to Minnesota. He stated he lived in Stanberry, Missouri, from 1914 to 1918 and that he owned an orange grove in Homestead, Florida, for ten years prior to 1945. He also had on his person a card indicating he had lived in Indianapolis, Indiana.

Itinerant Health Lecturer Pleads Guilty to Illegal Practice of Healing

Re: State of Minnesota vs. Edna Evans, also known as Fra'Zee Evans.

On July 16, 1948, Edna Evans, also known as Fra'Zee Evans, sixty-six years of age, giving her home address as 723 So. Mansfield, Los Angeles, California, entered a plea of guilty to an information charging her with the crime of practicing healing without a basic science certificate. The plea of guilty was entered before the Hon. Paul S. Carroll of the district court of Hennepin County, Minnesota. Upon recommendation of the county attorney and legal counsel for the Minnesota State Board of Medical Examiners, Judge Carroll imposed a fine of $500 or, in lieu of the fine, twelve months in the Women's Detention Home. Mrs. Evans paid the fine at once and told the Court that she had given her last health lecture.

Mrs. Evans was arrested July 15, 1948, after giving three health lectures at the Leamington Hotel, Minne-

Minnesota Academy of Medicine

Meeting of March 10, 1948

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, March 10, 1948. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 by the president, Dr. T. A. Peppard.

There were forty-four members and one guest present.

Minutes of the February meeting were read and approved.

The scientific program consisted of two theses.

MALIGNANCY OF THE SKIN

CARL W. LAYMON, M.D.
Minneapolis, Minnesota

Malignant neoplasms of the skin are usually of epithelial or connective tissue origin, the former being called epitheliomas and the latter sarcomas. Epitheliomas are far more common than sarcomas. In general, cutaneous malignancies possess features which are essentially injurious to the host and thus differ from benign new growths. Among these features are: tendency to infiltration, local destructive properties, formation of metastases, recurrence after removal, local interference with function and general toxic action of absorbed tumor products. In this paper the lymphoblastomas will not be considered.

Sarcoma

Malignant connective tissue tumors are rare in the skin. They are of various structural types such as the spindle, mixed, round celled or fibrosarcoma. They can occur on or beneath the skin anywhere but are especially frequent in the inguinal regions, thighs, and buttocks. They vary greatly in size from a few mm. to several cm., are soft or extremely firm, of the color of skin to red or bluish-red and are single or multiple. The clinical picture of cutaneous sarcoma is frequently nondiagnostic—hence histologic study is necessary. The prognosis depends upon the histologic findings and is fairly good in fibrosarcoma. In malignant and undifferentiated round-celled sarcoma metastasis may occur in the lungs, resulting in death. Surgical excision is the therapy of choice since most of these lesions are radioresistant.

Multiple Hemorrhagic Sarcoma of Kaposi.—The lesions in this special type of sarcoma are either doughy infiltrated plaques or pea to bean-sized reddish or reddish-purple nodules. Telangiectasia may be a prominent clinical feature. The individual lesions may persist, disappear or ulcerate. Almost all cases occur in males. The extremities are most frequently involved, especially the lower, although lesions may be present anywhere on the body. The course may be extremely rapid, death having been known to occur within a few months. The average duration of the disease is from five to ten years, although cases have been reported in which the course was as long as twenty-five years. Almost any organ in the body may be involved but especially the gastrointestinal tract, liver, lungs, and the retro-peritoneal and mesenteric lymph nodes. Anemia, eosinophilia, and monocytosis may be present. A combination of arsenic internally combined with judicious roentgen therapy is the most satisfactory method of treatment. Although complete cure is almost unheard of, life may be prolonged many years by proper treatment.

Dermatofibrosarcoma Protuberus.—This disorder usually begins with small, hard nodules, which gradually enlarge to form thick, sclerotic plaques. On the latter, tumors subsequently develop which are sessile, pedunculated or mushroom-like. Occasionally the lesions become ulcerated and form vegetating masses. The sites of predilection are the abdominal wall, chest, upper and lower extremities, back and inguinal regions. The treatment of choice is surgical extirpation.

Hemangio-Endothelioma.—A hemangio-endothelioma is a tumor possessing low-grade malignancy, a precise histologic structure and is composed essentially of blood spaces and vessels in different stages of development. The blood does not circulate through the tumor mass because of the immaturity of many of the vessels. True endothelioma of the skin does not exist, for the origin of an endothelioma must be from endothelially lined structures such as blood or lymph vessels; therefore, the so-called endothelioma of the external surface is either a hemangio-endothelioma or a lymphangio-endothelioma. Many so-called endotheliomas are really epitheliomas or sarcomas.

The tumor may occur on almost any part of the body. It varies in size from a few millimeters to several centimeters and is usually dark red in color. Most of these tumors are moderately soft in consistency and may or may not be surrounded by satellites. This type of tumor frequently ulcerates, usually following trauma, and bleeds profusely. Because of its infiltrative nature it may become attached to underlying structures such as cartilage or bone or to the overlying skin. In the latter case a pedunculated tumor may form. The lesion is usually not tender nor painful when manipulated.

The degree of local malignancy is variable. In some cases hemangio-endothelioma is definitely benign. Certain cases are malignant enough to penetrate deeply although the ability to metastasize is extremely low. It is questionable whether subsequent growths should be re-

---

From the Division of Dermatology, University of Minnesota, H. E. Michelson, M.D., Director, and the Dermatology Service, Minneapolis General Hospital, S. E. Sweitzer, M.D., and Carl W. Laymon, M.D., Chiefs. Inaugural Thesis read before the Minnesota Academy of Medicine, at its regular monthly meeting of March 10, 1948.

garded as metastases or lesions of multicentric origin. In most cases excision is sufficient to effect a cure, although hemangio-endotheliomas are responsive to radiation. Recurrence may occur although the recurrent tumor seems to be as amenable to treatment as the original growth. The prognosis as to life is good.

Epithelioma

Practitioners should never forget the following aphorism: in every patient over forty years of age one must rule out epithelioma in every plaque, nodule, or ulcer which doesn't heal within a reasonable period of time especially if the lesion is located on the face. The value of histologic examination cannot be overemphasized. The histologic types include basal cell, basal squamous cell and squamous cell epitheliomas. If the muco-cutaneous junctions are excluded, basal cell epitheliomas are more frequent than the squamous cell variety. If however one includes the muco-cutaneous junctions, squamous cell epitheliomas are more frequent on account of the relatively great number of epitheliomas of the lip. Mixed cell or basal squamous epitheliomas occur in from 10-20 per cent of the cases.

Approximately 80-90 per cent of all epitheliomas of the skin occur about the face and neck. Although certain locations may suggest the type of epithelioma, final diagnosis must depend upon the microscopic findings. As a rule basal cell epitheliomas occur most frequently about the nose, eyelids and the anterior portion of the face above the level of the nose. The squamous cell type occurs more frequently about the ears, on the posterior part of the face and below the level of the nose. Epitheliomas of the hands, lips, and genitals are almost invariably of the squamous cell type. In general, the basal cell variety progresses much more slowly than the squamous cell.

There are certain conditions which predispose to the development of cutaneous epithelioma, among which are radiodermatitis, dermatoses such as lupus erythematosus and lupus vulgaris, varicose ulcers, scars following burns and wounds, long exposure to sun and wind, the ingestion of arsenic and chronic irritation from substances such as tar and oil.

Epithelioma of the skin usually begins as a nodule which gradually enlarges to form a plaque which is characterized by peripheral activity in the form of a pearly border. The malignant cells usually outgrow the blood supply so that an ulcer sooner or later forms. There are several special types such as the scar, button, cystic, or rodent ulcer. Much more rapid growth and tendency to metastasize characterize the squamous cell variety. Histologic examination of all suspected epitheliomas is not only justified but urgently indicated. Scalpel surgery, irradiation, cauterization or desiccation are all effective in the treatment of epithelioma of the skin when properly used.

Superficial Epitheliomatosis.—This is a distinct type of epithelioma occurring occasionally as a solitary plaque but usually as multiple lesions limited as a rule to the trunk and face. There are two varieties: one dry, in which there are superficial scaly plaques somewhat resembling psoriasis but characterized by a very fine thread-like, elevated pearly border, and a second less common eczematoid type which suggests extramammary Paget's disease. Superficial epitheliomas usually perist either unchanged or slowly growing for many years. In the slow-growing types the lesions may be relatively radio-resistant so that destruction or excision is the therapy of choice. Other more rapidly growing lesions may respond to X-radiation.

Epithelioma of the Lip.—Epithelioma of the lip comprises one-third of all cutaneous epitheliomas. It occurs on the lower lip in 95 per cent of the cases and almost always after the age of fifty and almost exclusively in males. The lesions are indurated nodules with or without ulceration. In general, they may be divided into: (1) the papillary type which has a definite upgrowth from the surface, and (2) the infiltrative type which is a more penetrating variety. The lesions eventually metastasize to the submetal and submaxillary lymph nodes. About one-third of all patients who have epithelioma of the lower lip die even though the disease is easily cured if properly treated in the early stages. After metastasis has occurred the involved nodes compress the organs of the neck and become ulcerated and infected. Remarks concerning the therapy of epithelioma in general also apply to epithelioma of the lower lip. Either surgical excision, radiation or destruction suffice if thoroughly and properly done. Routine dissection of the lymph nodes of the neck is not advisable since many observers have found that if the lymph nodes are not palpable at the time the primary lesion is eradicated metastasis rarely occurs.

Xeroderma Pigmentosum.—Xeroderma pigmentosum is a rare disease which is characterized by hypersensitivity to light followed by hyperpigmentation, atrophy of the skin, telangiectases and warty and malignant growths. The disorder has its onset early in life, although occasionally it begins in adults. In most instances sunburn following mild exposures to light, signals the beginning of the disease. Following this intense freckling usually occurs on the exposed surfaces of the body. Later, dilatation of blood vessels, warty growths, and keratoses appear, and still later malignant changes occur, most commonly basal cell epithelioma but occasionally the squamous cell type. Photophobia and lacrimation are prominent symptoms. The course of the disease is variable, but in almost all cases, however, the patients ultimately die of cancer. No treatment had been found which affects the final outcome of the disease. The avoidance of exposure to sun and the use of protective lotions is urgently advised. The treatment of the epitheliomas which develop is the same as that of epithelioma in general.

Atypical Forms of Epithelioma

Bowen's Disease.—This disease is considered by some to be a precancerous dermatosis while others feel that it is a highly specialized form of superficial epithelioma. It was first described by Bowen in 1912 as a solitary lesion composed of large papules or nodules and re-

sembling a nodulo-ulcerative syphilid. The lesions are usually located on the trunk and run an extremely slow course. There may be discoid plaques or nodules which are firm, dark brown, and elevated. Ulceration may supervene. There is usually an arciform configuration. Cases have been reported in which squamous cell epithelioma eventually developed with metatasis and death. Surgical excision is the treatment of choice as the lesions are radio-resistant.

Paget's Disease.—Paget's disease is a specific and rare form of malignancy which manifests itself almost exclusively around the nipple, especially in the female sex although cases in males have been reported. It is characterized by an early eczematoid stage and the presence microscopically of peculiar hydropic cells although in some cases the lesions are dry and psoriasiform. The borders usually remain sharply defined and the area gradually becomes indurated and infiltrated. Retraction of the nipple may be present or absent. In practically all cases there is an underlying carcinoma of the breast either independent of the cutaneous lesions or extending and connecting with them in the form of an adenocarcinoma or intraductal carcinoma. Treatment therefore is surgical. Simple amputation of the breast or radical amputation plus dissection of the adjacent nodes may be indicated depending upon the findings.

Nevocarcinoma (melanocarcinoma or malignant melanoma).—This type of tumor is the most malignant and rapidly fatal of all cutaneous neoplasms. It usually begins as a dark brown or blue-black nodule from a few mm. to several cm. in diameter. A history of preceding pigmented nevus is obtained in from 30-50 per cent of the cases. Many observers believe that nevocarcinoma originates only from the epidermal-dermal type of nevus which has also been termed junction nevus. Nevocarcinoma, however, may develop from apparently normal skin. The lesions as a rule first metastasize locally developing firm, dark, satellite nodules. The adjacent lymph nodes involved next followed by metastasis to any of the internal organs but especially to the liver and lungs. Nevocarcinoma may develop at any age although the average is fifty years. The disease appears about equally in both sexes. This type of malignancy occurs especially on exposed surfaces, particularly the face and extremities and especially the feet. Attention should be called to a special type—the so-called melanotic whitlow which may resemble an ordinary felon but which is surrounded by pigmented spots or streaks. Radical excision is the treatment of choice. Prognosis of course depends upon recognition of the early stages of the disease.

In conclusion it may be said that malignancy of the skin can, in the majority of instances, be successfully treated either surgically or by a number of physical agents. Each case requires individualization since one can so frequently arrive at the same result by one or a combination of several methods. The well trained therapist should not be overly enthusiastic for one method and should be prepared to use the agent best suited for each case. He should in general use that method at which he is most adept, keeping constantly in mind that the first attack on cutaneous malignancy is usually the most effective and for this reason should be well chosen and if possible complete, so that further therapy will not be necessary. Insufficient treatment, whether it be surgical, roentgenologic or otherwise, is to be heartily condemned.

Discussion

Dr. H. E. Michelson, Minneapolis: I am very pleased and proud of Dr. Laymon's presentation of cutaneous cancer. I think those of us who deal with skin cancer look upon it more as a problem and not as a disease and, in so doing, we are not satisfied with our present status but try to improve things wherever possible. Two groups of doctors see skin cancer—dermatologists and general practitioners. There should be no great difference in their ability to diagnose skin cancer. It is a rather simple diagnosis. The only advantage we have is that we are more suspicious and more willing to perform a biopsy. Since we, as dermatologists, see many skin cancers, we have a distinct duty to the public and to the profession. I think the public has the right to expect of their doctors a written clinical and microscopic diagnosis and that their doctors should give them in writing just what treatment was given so that if the patient wishes to seek further advice or if there is a recurrence, they will have exact information about what was done. Our duty to the profession is to point out the shortcomings of present-day diagnoses and treatment and to not be satisfied but to continue to look for better treatment for there is much yet to be expected and we must not become content with what we are doing because the results seem to be good.

Dr. Paul O'Leary, Rochester: I have enjoyed Dr. Laymon's presentation very much. In almost twenty-five

years of experience with the grading of epitheliomas, as suggested by Dr. Broders, I have learned to place much faith in it. In an individual with a grade 3 or 4 carcinoma about the mouth, it gives me much satisfaction when glandular dissections are done of the area drained by the malignancy. All lesions that appear to be basal cell epitheliomas clinically are not so under the microscope and for the occasional case in which the microscope reveals a higher degree of malignancy than was suspected clinically, a more radical therapeutic procedure accordingly results in a higher incidence of cure.

One more point that I would like to discuss very briefly is my recent experience with the use of sodium pteroyl triglutamate, under the trade name of Teropterin, in the treatment of cutaneous malignancy. You may recall that at the meeting of the American Chemical Society last year there was some publicity given as to the value of this remedy for treatment of cancer. I have used it only in individuals in whom x-ray therapy and surgical procedure were no longer advisable either because of the extent of the lesion and metastasis or because x-ray therapy had been given to the limit. In other words, we have used it essentially in cases which were hopeless. I have treated some twenty-eight cases, including five with metastatic melanoma, without any encouragement. Today, however, I saw a woman whom we treated last fall, who had a primary melanoma in the cheek with a large gland in the side of her neck, diagnosed under the microscope. When treatment was started she had some metastatic nodules elsewhere throughout the skin and following treatment she said the nodule at the angle of the jaw (in other words, the original metastatic lesion from the primary) had disappeared. Unfortunately, however, in spite of the disappearance of this lesion she has continued to develop other metastases in her skin.

There have been no reactions from the Teropterin; in fact, it seems to be quite an inert product. I have been informed that there are several cases in Boston which have been under treatment for more than a year, in which it would appear that metastasis had been arrested, but the patients are still under observation.

Dr. John Madden, Saint Paul (by invitation): I think that everything that need be said has been said. I enjoyed Dr. Laymon's presentation very much.

Dr. F. W. Lynch, Saint Paul: Dr. Laymon has thoroughly and completely discussed the subject of malignancy of the skin. In such a discussion one must always face the question as to the most suitable treatment. It seems evident that carcinoma of the skin is going to be treated not only by dermatologists, but also by surgeons, radiologists, and general practitioners. A treatment that is most effective in the hands of one specialty may prove to be less so in the case of another group of physicians. Even within a specialty there will be individuals who will give more effective treatment by one method than by another. In general, the best results will be obtained by using the method with which one is most familiar. This is not entirely true and the best therapist will be the person who is capable with several methods of treatment and can choose from them. When an individual cannot use several methods, it is probably better that there be frequent reference of patients to other physicians.

Dr. Michelson commented on the importance of the individual and his response to the carcinoma. Dr. Leven will clearly recall a patient whom I have seen with him. This patient has basal cell carcinoma proved by repeated biopsies, but the process is obviously highly malignant in the sense that the lesions infiltrate widely and deeply in spite of the microscopic appearance of relatively benign tumor cells. This is the most obvious example that I have seen with such a complete lack of resistance to invasion by carcinoma of a basal cell type. It seems likely that there are great variations in the individual's response in other cases. In the treatment of cancer there are, then, several points to consider: first, the physician with his past experience, technical abilities, and available equipment; second, the lesion with its clinical features of invasiveness, destructive tendency, or hypertrophic growth. The microscopic nature of the lesion is also highly important. Thirdly, the response of the individual to the carcinoma can often be judged by the clinical appearence of the lesion, but this will not be true when the lesion is in an early stage of development. Choice of treatment must be dependent upon an analysis of these factors which have been listed. The highest effectiveness will be achieved by early and highly skilled treatment.

Dr. S. E. Sweitzer, Minneapolis: I want to congratulate Dr. Laymon—there is not much more that can be added to the paper. My view of these epitheliomata is that some doctor has seen them and dismissed them as not amounting to very much, and said that we will watch them. There is no reason for watching. These lesions should be biopsied and proper diagnosis made, and treatment started right away. Then we will not see any of these neglected cases with such extensive involvement.

Dr. Carl Laymon, in closing: There is very little to add and I thank all of the men for their discussions. I think Dr. O'Leary's point regarding the grading of epitheliomas is well taken. It is an important additional help in the appraisal of the case under consideration. It should be emphasized that a patient who has had an epithelioma of the skin is apt to develop other lesions at other sites at a later time even though the initial lesion has been successfully treated.

I thank the members for the privilege of being here.

OCULAR PSYCHONEUROSIS WITH PARTICULAR REFERENCE TO ANXIETY REACTIONS

EDWARD P. BURCH, M.D.

Saint Paul, Minnesota

It has been stated with considerable justification that an uncomfortable eye very frequently mirrors an uneasy soul. Despite this observation a survey of modern ophthalmic literature including current, standard textbooks clearly indicates that comparatively little has been written concerning ocular disorders of psychogenic origin. The majority of publications in this field deal with the conversion syndrome of hysterical blindness and its spectacular manifestations of motivated disregard of visual impressions, tubular fields and corneal anesthesia. Apparently very few efforts have been made by ophthalmologists to attempt an integration of commonly observed ocular complaints and symptoms into the fabric of such psychoneurotic states as psychasthenia, neurasthenia, reactive depression, hypochondriasis, and anxiety-tension reactions.

This deficiency in ophthalmic literature is quite striking in contrast to the numerous, well-known, and important contributions which have been made by cardiologists and gastro-enterologists, for example, to a better understanding of the somatic manifestations of functional disorders.

It might be of interest to consider some of the reasons why there exist so few articles dealing with the relation-

Inaugural Thesis.

ship between psychoneurotic states and the visual apparatus. It cannot be attributed to lack of experience, for ocular complaints, unmistakably of functional genesis, are encountered almost daily in ophthalmic practice. Nor can it reasonably be ascribed to insularity on the part of ophthalmologists, for routine examination of the fundus oculi frequently leads to a diagnosis of systemic disease such as diabetes, arteriosclerosis, hypertension, nephritis, brain tumor, multiple sclerosis, blood dyscrasia and other maladies of a constitutional nature too numerous to mention.

It is, of course, true that the majority of ophthalmologists are relatively unskilled in the art of psychiatric history-taking and interrogation. It is perhaps equally true that quite generally ophthalmic histories leave something to be desired insofar as completeness is concerned. Rarely, for example, is the question of the family history accorded adequate treatment in the questioning of ophthalmic patients. Yet in a history of blindness in a parent or sibling may be found the underlying cause of a profound disturbance of the personality.

In the training of ophthalmologists much stress is necessarily placed upon the acquisition of facility in the use of diagnostic instruments of precision and accuracy. The ophthalmologist therefore tends to place great emphasis upon findings and data acquired through purely objective diagnostic procedures. As a consequence he is often inclined to think in terms of organic disease entities and to arrive at a diagnosis of a functional disorder only secondarily and by exclusion rather than by a dynamic approach to the problem. It is also a fair presumption that the doctor-patient relationship of the ophthalmologist frequently differs to a considerable degree as compared with that enjoyed by the family physician or internist. There is still another aspect of ophthalmic practice which is inimical to a realistic evaluation of the psychoneuroses, and borderline psychoneurotic states. The great majority of patients who consult an oculist anticipate that a very tangible and concrete explanation of their symptoms together with a definite solution of their particular problem will be accorded them at the conclusion of the eye examination. It seems conceivable that this aspect of the practice of diseases of the eye may have conditioned the attitude of many ophthalmologists, particularly those who each day perform a large number of refractions, with respect to the final disposition of patients whose symptoms are antithetical to the clinical findings. It is simply much easier to change a pair of glasses than a way of life.

Under ideal conditions of medical practice it would obviously be desirable to obtain a psychiatric consultation upon all patients who exhibit psychoneurotic traits. So great is the misunderstanding of many patients, however, even in this era of widespread dissemination of medical knowledge in the public press, that unless it is managed with considerable skill and tact, the suggestion that a psychiatric consultation is in order may evoke a reaction of considerable resentment on the part of the patient. It is sometimes quite necessary to resort to an elaborate build-up and even fanciful explanation of need for psychiatric consultation before certain categories of patients can be persuaded to avail themselves of the advantages of management by our psychiatric colleagues.

The large number of patients whose illness is partly or wholly of a functional nature, however, precludes the possibility of referring all such individuals to the rather small number of available psychiatrists and internists who are skilled in the handling of psychosomatic disorders. Many of the borderline and milder psychoneurotics can and should be treated at first hand, reserving the more difficult problems for the psychiatrist.

In recent years, partly as the result of more intensive psychiatric instruction at the undergraduate level and partly as a consequence of a more compelling interest in psychosomatic disorders stemming from the experiences of World War II, the management of psychosomatic disorders by the medical profession at large has improved appreciably in recent years. It must be acknowledged that the armed forces accomplished a great deal in ameliorating the attitude of many physicians with respect to mental disorders of all types, particularly the psychoneuroses. Credit is also due the policymakers of our medical schools for the powerful influence they have exerted in emphasizing the importance of psychologic medicine.

In the military service during World War II an unprecedented opportunity of acquiring a vast amount of data concerning the incidence of the various types of ocular psychoneurosis unfortunately was lost through lack of a centrally directed program of clinical research. Since nearly 40 per cent of all medical discharges from the Army were due to psychiatric states, principally psychoneurosis, it can readily be appreciated that there was no dearth of material. In all the larger medical installations, competent psychiatric examiners were available as consultants. Furthermore, any difficulty in persuading the patient to accept psychiatric attention could be expeditiously resolved. While it is to be regretted that no formal study of the incidence of the ocular psychoneuroses was ever undertaken, certain impressions come readily to mind. At one of the large Army eye centers, O'Reilly General Hospital, located in Springfield, Missouri, neuro-psychiatric consultations were requested upon a very large number of eye patients. Very few instances of ocular hysteria were encountered. Malingering, which is, of course, a psychopathic trait and therefore does not fall within the purview of this discussion, was also uncommon. The great majority of patients referred to the psychiatrist were found to be suffering from anxiety reactions of varying profundity, although not infrequently an admixture of other psychoneurotic states, particularly neurasthenia, and hypochondriasis was also present. Obsessive-compulsive states and reactive depressions were seldom encountered in patients assigned to the eye service.

While no precise figures are available in existing ophthalmic literature, impressions gained from private practice indicate that of the various psychoneuroses, anxiety reactions are more common in the field of ophthalmology than other varieties. They may be sufficiently severe to constitute a major problem in their clinical management. It is the purpose of this thesis to examine and discuss anxiety-reactions having an ocular basis, to speculate upon their pathogenesis, to enumerate

some of the more commonly encountered ocular symptoms, and to elaborate upon measures which are regarded as of value in their treatment.

An anxiety state should be looked upon as one which occurs in a patient who is otherwise mentally normal, and which is either directed toward some object or situation which under ordinary circumstances does not evoke such a reaction, or else one which is experienced as an undirected emotional state, the cause of which the patient is unable to comprehend. Psychiatric research has demonstrated that an apparently misdirected or undirected anxiety reaction almost invariably arises in circumstances for which an intelligible explanation can be found. In some instances a total psychobiological survey of the patient may be required, including a longitudinal life history and even psychoanalytical studies.

Anxiety of psychopathologic proportions can arise from conditioned stimuli. The well-known experiments of Pavlov have conclusively established such a possibility. Many of the phobias, for example, owe their origin to conditioned stimuli. The environment or setting in which the initial symptoms occur, while not of necessity their origin, may serve as a conditioned stimulus. Such a stimulus is quite capable through the mechanism of association, of exciting the emotion of anxiety although the patient himself may have forgotten the original cause.

Anxiety states may also be induced by suggestion and even directed toward a situation which ordinarly should occasion no cause for alarm. Fears, acquired in early childhood, have frequently persisted into adult life as the result of injudicious and ill-advised remarks or suggestions from parents, nurses, teachers and playmates.

Anxiety states may also arise in a dissociated form where the anxiety is so completely dissociated from its original source that the source is no longer recognized as its cause. Such dissociation of the emotion from its cause is explained by the psychological phenomenon of repression. According to the Freudian School, many, if not the majority of anxiety neuroses, are attributable to a repressed infantile attachment to the parent of the opposite sex.

In addition to the three aforementioned types of anxiety, psychiatrists recognize a fourth type which they term constitutional anxiety. In some individuals anxiety constitutes the customary or habitual reaction to a large part of their environment. It has been said of such persons that it is not the threat which is serious, but the self which is vulnerable. This form of anxiety becomes established very early in life and is often the outcome of a deeply-rooted sense of inferiority. It is considered to be the product of situations which obtain in family life during childhood and early adolescence. Competition between children for the affection of their parents may lead to anxiety neurosis, or it may develop through association with emotionally unstable, tyrannical or alcoholic parents. The psychologic patterns thus established in early life become perpetuated in the reactions of later years. Since anxiety reactions, involving the eye, almost invariably are characterized by mental and physical manifestations as well, it seems desirable to mention some of the more important signs and symptoms which enable the clinician to arrive at a diagnosis.

The outstanding symptom, of course, is anxiety. Such apprehensiveness may be either quite constant and diffuse or it may occur in paroxysmal intensifications resulting in a state of utter panic. Irritability, insomnia, vertigo, inability to concentrate, vague feelings of depression and nightmares are other commonly encountered symptoms. Occasionally patients complain of a sensation of pressure at the vertex or a sensation of falling through space. Anorexia is not at all uncommon. Tachycardia, diarrhea, frequency of micturition, and profuse sweating may occur and point to over-activity of the sympathetic nervous system.

Upon physical examination the blood pressure is usually subnormal, the pulse rapid, the extremities cold and clammy; the pupils are often dilated but there is no disturbance of their reaction to light or accommodation. Exaggerated tendon reflexes may be elicited. Anxiety neurosis must be distinguished from vaso-vagal attacks, angina pectoris, organic brain disease, particularly senile changes due to arteriosclerosis, agitated depression and in some instances schizophrenia, especially in its early stages. Of the other psychoneuroses it is more often confused with neurasthenia with which it has certain subjective symptoms in common.

The eye, since it contains within itself nearly all of the functional components upon which personal maladjustment and emotional events are capable of being reflected, readily lends itself to the production of symptom-complexes occasioned by psychological stresses and strains. In illustration and support of this viewpoint it is only necessary to recall that not only the reception of sensory impressions, but also the voluntary contraction of striated muscles and the involuntary contraction of unstriped muscle all may and do occur in the visual apparatus. One may therefore expect to encounter a wide range of ocular symptoms which are predicated upon disturbances of the psyche.

Among the essentially ocular complaints which characterize the patient suffering from anxiety neurosis, fear of blindness, fear of some specific eye disease, and fear of inability to use the eyes without incurring serious impairment of vision are the most striking. This is particularly true of patients who have lost the vision of one eye, in patients with early cataract, glaucoma, and macular disease, and is also encountered in patients suffering from amblyopia exanopsia. Pain, in and about the eyes, sometimes vaguely described and of a diffuse nature but occasionally definitely localized back of the eyes, and of great intensity, are also suggestive symptoms. Headache, occuring in anxiety neurosis, is frequently represented by the patient as an intolerable sense of pressure and is often localized at the vertex or some equally definite anatomic location. Inability to read or perform any type of close work except for a very brief time is a common symptom. Upon careful questioning the fact will usually be elicited, however, that such incapacity is due to a lack of concentration, a preoccupation of the patient with his fears, rather than the nervous asthenopia which is so prominent a feature of the neurasthenic personality.

Photophobia, unaccompanied by demonstrable signs of either external or intraocular inflammatory disease, constitutes an occasional ocular symptom in anxiety neurosis. The patient often presents himself wearing deeply tinted lenses. Examination of the eyes can sometimes be carried out with only the greatest difficulty because of the patient's aversion to exposure of the eyes to the ophthalmoscope or slit lamp beam. Even after instillation of local anesthetics the patient may resist efforts to proceed with the examination.

Frequent inctitation or blinking, while commonly noted in hysteria, is also seen in patients suffering from anxiety-tension states. It should not be confused with the essential blepharospasm of hysteria or senile blepharospasm. In the former condition other indices of hysteria are present while the latter condition occurs in individuals of advanced years and anxiety is not a prominent feature of the symptomatology.

Indecisiveness during the subjective examination for glasses is another characteristic of anxiety reactions, especially if marked. While a certain amount of hesitancy in responses as to whether a certain lens improves or fogs the vision is a common occurrence, the psychoneurotic patient with an anxiety reaction nearly always displays unusually great indecision and frequently volunteers the remark that he is afraid that faulty judgment on his part will result in receiving lenses that will be harmful to his eyes. This tendency is so evident in extreme instances that recourse to entirely objective examinations becomes desirable.

In dealing with psychoneurotic patients of any category, it becomes vital to achieve a proper assessment of emotional factors. The frank attitude that either the illness is mental or physical will inevitably lead to pitfalls. The establishment of good rapport between doctor and patient is of unusual importance. Failure to achieve such a rapport leads to a conviction on the part of the patient that the physician is either uninterested or insincere. It has been said of failure to establish a sound relationship, that while the patient may not know the cause of his difficulty he knows how he feels while the doctor knows the cause of the difficulty but does not know how the patient feels. An adequate history is obviously of extreme importance and for the ophthalmologist who is called upon to deal with anxiety states the family history with respect to the incidence of heredofamilial ocular disease should not be overlooked. Repeated examinations and oversolicitude on the part of the examiner should be sedulously avoided. Also superficial and hasty examinations and an attitude that the patient's illness is either of a mysterious or illusory character.

The eye examination must be sufficiently comprehensive and thorough, not only to exclude organic disease but also to impress the patient with the fact that the ophthalmologist is seriously interested in his complaints. Ill-advised haste and superficiality will only serve to arouse the thought that very possibly the true cause of the illness has been overlooked. An unsympathetic attitude will drive the patient to either a more understanding oculist or into the hands of some cultist or irregular practitioner.

It is, of course, quite possible to overlook organic disease of the eye and ascribe the patient's symptoms to a functional etiology. There are several eye diseases which may be misdiagnosed through errors of omission or lack of awareness on the part of the ophthalmologist. One of the most common is imbalance of the extraocular muscles, particularly vertical imbalances. The possibility of such imbalances should be borne in mind in patients with high degrees of anisometropia where a prismatic effect is produced by the lenses. Early glaucoma requires extremely meticulous care in examination, especially of the central field of vision, as recently emphasized by Hendrie Grant. The value of provocative tests should not be underestimated as a means of detecting very early glaucoma. Recurrent erosion of the cornea, causing severe and sharp pain, especially at night, is occasionally discounted as of no consequence and attributed to a psychoneurosis. Other corneal lesions such as superficial punctate keratitis and Sjogren's syndrome, or keratitis sicca, may fail to be recognized through failure to make an examination under the slit lamp. This last-named disease occurs most frequently in women about the time of the menopause and may be accompanied by arthritis and xerostomia. There is a deficiency of tears and examination of the cornea will usually reveal loose filaments of corneal epithelium. A foreign body sensation and photophobia are the usual complaints. The severity of the patient's complaints may seem at considerable variance with the findings uncovered at a single examination unless a Schirmer test to measure the rate of flow of tears is carried out.

Doubtless there are other rather uncommon eye diseases of obscure etiology which may escape detection and cause patients labeled as psychoneurotics to wander from physician to physician seeking relief. This brings to mind one of the bete noirs of the ophthalmologist. Reference is made to the patient who has wandered from refractionist to refractionist, seeking a pair of comfortable spectacles. Usually such individuals have a dozen or more pair of glasses, all approximately of the same strength, and usually indicating the presence of only a low-grade refractive error. They almost invariably have a plethora of eye symptoms which they apparently take great pleasure in reciting with infinite circumstantiality. Often the complaints have been written down and not infrequently they are couched in medical phraseology. They will readily admit to a host of symptoms inplicating other systems of the body. Some of them practically defy the oculist to provide them with a comfortable prescription for lenses. Prompt psychiatric care is invariably indicated for such hypochondriacal individuals.

The treatment of anxiety neurosis should be prompt and always directed primarily toward the goal of discovering the cause for the patient's anxiety. It is sometimes possible for the ophthalmologist, if he has established good rapport, to uncover significant psychiatric data. Judicous questioning concerning the patient's attitude toward health, employment, marital, educational, religious and family problems and difficulties may bring to light situations and conflicts which have an important bearing upon the neurosis. If meaningful information is

disclosed, the next step will be to interpret and explain to the patient his symptoms in relationship to the basic causative factors. This explanation should be couched in simple non-technical language. An attempt can then be made to persuade the patient to reorient his emotional reactions toward the cause of his apprehensiveness.

Since a fear of blindness is so commonly the focal point around which ocular psychoneuroses revolve, particularly in patients suffering from early cataract, glaucoma or macular degenerative lesions, great caution must be observed in discussing the findings to avoid aggravation of the neurosis.

In anxiety reactions of short duration, especially if a definite cause is found, the cure may often be effected at the ophthalmological level through a rational interpretation of the patient's symptoms. It is quite feasible by giving the patient insight to induce him to exhibit a healthier attitude toward his illness.

On the other hand if the ophthalmologist recognizes the anxiety reaction as one of considerable duration, if questioning concerning the usual etiological factors fails to elicit significant psychological content, upon which a therapeutic effort can be based, or if he feels himself incompetent to undertake therapy, psychiatric consultation becomes imperative. Placebos, including a prescription for glasses, except as an interim measure of dubious value, should not be resorted to by the ophthlmologist since their efficacy is but transitory and often destroys the faith of the patient.

Chronic anxiety states, particularly those which are founded upon dissociation and repression or have been initiated by conditioned stimuli will ordinarily require psychiatric consultation and management. Psychoanalytical studies or some modification or variant thereof may prove useful in the unmasking of subconscious mental processes.

Since it is well understood, particularly in the military service, that certain psychoneurotic patients derive a definite personal gain or advantage from their illness it is apparent that a cure is sometimes difficult or impossible of achievement, even after a prolonged regimen of individual psychotherapy.

As an integral phase of the intensive reconditioning program of the Army, mass or group psychotherapy was instituted for psychoneurotic patients during World War II. Lectures and group discussions, employing the question- and answer-method were widely used at general and large station hospitals. Group psychotherapeutic techniques appeared to be of definite value for mild and borderline psychoneurotics, but seemed to retard the progress and even aggravate the condition of severe psychoneurotics. Very possibly the lack of motivation, which unquestionably existed to a rather alarming degree at times, accounts for the fact that mass psychotherapy in the Army was not an unqualified success. It has undoubtedly been of value in civilian practice when conducted under the proper auspices and with the judicious selection of patients. Considering the high incidence of psychoneurosis in civilian practice it seems worthy of further trial as an ancillary measure in our efforts to promote better mental health.

Discussion

DR. BURCH, in closing: In reply to Dr. Peppard's question. I think that is very true, individuals suffering from ocular psychoneurosis do have specific complaints which indicates that they are suffering from more than just the eye manifestations. One other remark—often oculists are not careful as to what they tell people who have a senile macular degeneration. They tell them nothing can be done. While it is true that they will lose their central field of vision and their ability to read fine print, very frequently the process is so slow that they will retain some useful vision that will help them to get about. They will not become dependent upon others for getting around. I think the same thing applies to other types of organic eye disease—one has to be extremely careful in dealing with this type of patient for fear of initiating a train of events that upsets the patient's emotional stability.

I wish to thank you for the privilege of coming here tonight and presenting this paper.

The meeting was adjourned.

A. E. CARDLE, *Secretary*

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

(Continued from Page 915)

apolis. The defendant charged $15 for the series of three lectures which were attended by about forty women, including two policewomen. Mrs. Evans had planned on giving another lecture, the evening following her arrest, for which she intended to charge $5 but was unable to do so. Mrs. Evans stated she came to Minneapolis, June 30, from Lead, South Dakota, and contacted a so-called health food store for the purpose of advertising their products. During her talks Mrs. Evans discussed various ailments, including diabetes, arthritis, neuritis, menstrual disorders and dietary deficiencies. The defendant would then recommend certain vitamins, medicines and health foods.

The defendant stated she was born in Jay County, Indiana, and had less than a high school education. She further stated that she had operated a millinery shop in Storm Lake, Iowa, for ten years prior to taking up health lecture work. Mrs. Evans claims to have been in health lecture work for the past fifteen years and admitted having been arrested in Indianapolis, Indiana, in 1942 on a similar charge. The defendant likewise admitted that she had no license to practice healing in any state. She was accompanied to Minneapolis by her daughter, Wanda.

Reports and Announcements

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The program for the annual meeting of the Northern Minnesota Medical Association, held August 20 and 21, in Duluth, is as follows:

Friday, August 20

"Ectopic Pregnancy, with Report of a Case of Ovarian Pregnancy" by Dr. Wilford J. Deweese, Bemidji.

"Major Points in Reading Electrocardiograms" by Dr. Arthur C. Kerkhof, Minneapolis.

"Recent Advances in Surgery of the Colon" by Dr. B. Marden Black, Rochester.

Noon Luncheon: F. Manley Brist and Dr. A. J. Chesley, speakers.

"Burns" by Dr. N. Logan Leven, Saint Paul.

"Congenital Retrolental Fibroplasia" by Dr. Earl E. Barrett, Duluth.

"Intussusception in Infancy and Childhood" by Dr. Tague C. Chisholm, Minneapolis.

"Medical Diagnosis in General Practice" by Dr. Walter C. Alvarez, Rochester.

Evening Banquet: Remarks by Dr. A. E. Cardle, president, and Dr. E. M. Hammes, president-elect, Minnesota State Medical Association. Principal address by the Honorable Joseph H. Ball, Senator from Minnesota.

Saturday, August 21

"Clinical-Roentgen-Pathological Conference" planned and arranged by Dr. Henry G. Moehring and Dr. E. L. Tuohy, Duluth.

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

The annual meeting of the Southern Minnesota Medical Association will be held on September 13 at Winona.

Dr. C. L. Sherman, Luverne, is president of the association, and Dr. W. A. Merritt, Rochester, is secretary. Dr. A. E. Meinert, Winona, is chairman of the local Committee on Arrangements. The following scientific program is planned:

Morning

"Three Cases of Scurvy" by Dr. Charles W. Rogers, Winona.

"Common Eye, Ear, Nose and Throat Conditions" (in Kodachrome transparencies) by Dr. George L. Loomis, Winona.

"Complications of Injuries to Blood Vessels" by Dr. James M. Janes, Rochester.

"Carcinoma of the Cervix: Treatment and Aftercare" by Dr. Hilmar R. Schmidt, Winona.

"Colles' Fractures and Their Treatment in General Practice" by Dr. Roger G. Hassett, Mankato.

"A New and Satisfactory Operation for Procidentia" by Dr. Arthur E. Benjamin, Minneapolis.

Afternoon

Case Reports:

"Perirectal Abscess Producing Symptoms of Generalized Peritonitis" by Dr. W. C. Bernstein, Saint Paul.

"Adrenal Cortex Tumor with Masculinization" by Dr. F. E. B. Foley, Saint Paul.

"Unusual Abdominal Injury" by Dr. W. E. Wilson, Northfield.

"Management of Acute Renal Failure" by Dr. Howard M. Odel, Rochester.

"Surgical Treatment of Prostatic Obstruction" by Dr. F. E. B. Foley, Saint Paul.

"Glomus Tumors" by Dr. J. Grafton Love, Rochester.

"Eye Problems in Infancy and Childhood" by Dr. V. L. Lindberg, Minneapolis.

SOUTH DAKOTA CANCER SYMPOSIUM

The South Dakota Division of the American Cancer Society, in co-operation with the South Dakota State Board of Health, is presenting a cancer symposium at the Coliseum, Sioux Falls, South Dakota, on October 11, 12 and 13. Physicians and dentists of Minnesota, Iowa, Nebraska and South Dakota are invited to attend. There is no registration fee. The following program is scheduled:

Tentative Program

October 11, 1948—Morning

9:00 A.M.

Dr. Brewster S. Miller, New York City. Assistant Medical Director, American Cancer Society.
"The American Cancer Society."
Dr. Robert L. Cherry, Kansas City, Missouri. Senior Surgeon, U. S. Public Health Service.
"Role of the Public Health Service in Cancer Control."
Dr. Cornelius P. Rhoads, New York City, Memorial Hospital.
"Present Status of Cancer Research."
Dr. John R. McDonald, Rochester, Minnesota. Pathologist, Mayo Clinic.
"Status of the Papanicolaou Stain for the Diagnosis of Cancer."
Dr. Elbert DeCoursey, Ft. Sam Houston, Texas. Colonel M.C., Chief, Laboratory Service.
"Pathological Diagnosis of Cancer."

Afternoon

2:00 P.M.

Dr. John R. McDonald, Rochester, Minnesota. Pathologist, Mayo Clinic.
"Pathology of Tumors of the Head and Neck."
Dr. Douglas Quick, New York City. Surgeon.
"Diagnosis and Treatment of Tumors of the Mouth, Accessory Sinuses and Salivary Glands."
Dr. Max Cutler, Chicago, Illinois, Oncologist—Chicago Tumor Institute.
"Radiological Treatment of Neoplasms of Head, Neck and Larynx."
Dr. Ferdinand C. Helwig, Kansas City, Missouri. Pathologist. St. Lukes Hospital.
"Special Pathology of Thyroid Tumors."
Dr. Arnold S. Jackson, Madison, Wisconsin. Surgeon—Jackson Clinic.
"Treatment of Thyroid Tumors."

Evening—Open To Laity

8:00 P.M.

Dr. Cornelius P. Rhoads, New York City.
"Future Outlook of Cancer."
Dr. Douglas Quick, New York City.
"Early Diagnosis of Cancer of Head and Neck."
Dr. Elbert DeCoursey, Ft. Sam Houston, Texas.
"The Destructive Effects of Radiation. The Modern Treatment of Cancer."

(Continued on Page 926)

amebiasis

...now endemic in the U. S.?

Formerly considered a tropical disease, amebiasis is more recently reported[1, 2] as "extremely common" and even "endemic" in this country.

Because early treatment has such an important bearing on prognosis, investigators stress the importance of prompt recognition through careful stool examination.

Destructive to the cysts of Endamoeba histolytica and especially valuable in sterilizing "cyst-carriers" is the high-iodine-containing amebacide, DIODOQUIN.

Diodoquin[3] "is well tolerated....It can readily be taken by ambulant patients and, therefore, eliminates the necessity of hospitalization."

SOUTH DAKOTA CANCER SYMPOSIUM

(Continued from Page 924)

October 12, 1948—Morning

9:00 A.M.

Dr. John V. Goode, Dallas, Texas. Professor Surgery, Southwestern University Medical School.
"Diagnosis and Treatment of Neoplasms of the Skin and Fascia, Including Hands and Feet."
Dr. Charles L. Martin, Dallas, Texas. Radiologist, Martin X-Ray and Radium Clinic.
"Radiological Treatment of Neoplasms of Skin."
Dr. Murray M. Copeland, Washington, D. C. Professor of Oncology, Georgetown University Medical Center.
"Benign Tumors of the Breast."
Dr. William Crawford White, New York City. Surgeon Roosevelt Hospital.
"Malignacies of the Breast."
Dr. Max Cutler, Chicago, Illinois. Oncologist, Chicago Tumor Institute.
"Radiological Treatment of Malignancies of the Breast."
Dr. Edwin Bayrd, Rochester, Minnesota. Department Medicine, Mayo Clinic.
"Lymphomas."

Afternoon

2:00 P.M.

Dr. Charles G. Johnston, Detroit, Michigan. Professor Surgery, Wayne University Medical School.
"Pre- and Post-operative Care of the Patient with Malignancy."
Dr. Ferdinand C. Helwig, Kansas City, Missouri.
"Pathology of Pulmonary and Mediastinal Tumors."
Dr. Thomas J. Kinsella, Minneapolis, Minnesota. Surgeon.
"Treatment of Pulmonary and Mediastinal Tumors."
Dr. Robert E. Fricke, Rochester, Minnesota. Radiologist, Mayo Clinic.
"Radiological Treatment of Chest Tumors."
Dr. Ernest Sachs, St. Louis, Missouri. Neuro-Surgeon, Barnes Hospital, Washington University Medical School.
"Neoplasms of Cranial Nerves, Spinal Cord and Peripheral Nerves."

Evening—Open To Laity

8:00 P.M.

Dr. William Crawford White, New York City.
"Tumors of the Breast."
Dr. Brewster S. Miller, New York City.
"The American Cancer Society and the Laity."

October 13, 1948—Morning

9:00 A.M.

Dr. Murray M. Copeland, Washington, D. C.
"Pathology of Bone Tumors."
Dr. Henry C. Marble, Boston, Massachusetts. Surgeon, Massachusetts General Hospital.
"Diagnosis and Treatment of Bone Tumors."
Dr. Charles L. Martin, Dallas, Texas. Radiologist, Martin X-Ray and Radium Clinic.
"Radiological Treatment of Bone Tumors."
Dr. Joe V. Meigs, Boston, Massachusetts Gynecologist, Vincent Memorial Hospital.
"Surgical Treatment for Cancer of the Cervix and Fundus Uteri."
Dr. Robert E. Fricke, Rochester, Minnesota. Radiologist, Mayo Clinic.
"Radiological Treatment of Carcinoma of the Cervix and Fundus Uteri."

Afternoon

2:00 P.M.

Dr. C. D. Creevy, Minneapolis, Minnesota. Professor Urology, Minnesota University Medical School.
"Diagnosis and Treatment of Malignancies of the Bladder and Prostate, Kidneys and Testicles."
Dr. Robert E. Fricke, Rochester, Minnesota. Radiologist, Mayo Clinic.
"Radiological Treatment of Malignancies of the Bladder, Prostate, Kidneys and Testicles."
Dr. Karl A. Meyer, Chicago, Illinois. Surgeon, Cook County Hospital.
"Carcinoma of the Upper Gastrointestinal Tract."
Dr. Raymond W. McNealy, Chicago. Chief Surgeon, Wesley Memorial Hospital.
"Carcinoma of the Colon and Rectum."

AMERICAN CANCER SOCIETY PUBLICATIONS

The American Cancer Society announces production of a series of illustrated monographs designed for wide distribution to general practitioners on the early recognition of cancer. These will be in brochure form profusely illustrated in color, and will be written by physicians of highest competence in their specialties.

The American Cancer Society plans to distribute these as widely as possible to physicians of our country in order to bring to mind again value of recognition of cancer by the general practitioner and his responsibility in correct diagnosis and early treatment.

These will be distributed to physicians by the American Cancer Society on a complimentary basis. The Minnesota Division of the American Cancer Society is now preparing a mailing list to receive these brochures. Any physician and surgeon in Minnesota can obtain these brochures as they are produced by writing to: Minnesota Division, American Cancer Society, Inc., 622 Commerce Bldg., St. Paul 1, Minnesota.

The American Cancer Society is publishing abstracts of current literature on cancer, prepared by the abstract section of the new journal, *Cancer*. The abstracts appear in volumes entitled "Cancer Current Literature." The first number in Volume 1 appeared in January, 1948. The publication attempts to present a listing and/or abstracts of all published research and clinical observations on cancer which have appeared throughout the world. Physicians may obtain copies upon application to the American Cancer Society, 47 Beaver Street, New York 4, N. Y.

MISSISSIPPI VALLEY MEDICAL SOCIETY

The thirteenth annual meeting of the Mississippi Valley Medical Society at Springfield, Illinois, September 29, 30 and October 1, will feature three full days of lectures and exhibits by members of the faculty of a large group of the leading medical schools and hospitals of this country. The medical schools represented include, Washington University, St. Louis University, University of Chicago, University of Minnesota, Northwestern University, University of Illinois, State University of Iowa, Baylor University and Loyola University. The entire scientific program and forty technical and scientific exhibits have been planned to appeal to the physician in general practice.

No registration fee will be charged, and every ethical physician is cordially invited to attend. The entire meeting will be held in the Abraham Lincoln Hotel. A detailed program may be obtained from the Secretary, Harold Swanberg, M.D., 209-224 W.C.U. Bldg., Quincy, Illinois.

MISSISSIPPI VALLEY MEDICAL EDITORS' ASSOCIATION

The fifth annual meeting, Mississippi Valley Medical Editors' Association, will be held at the Hotel Abraham Lincoln, Springfield, Illinois, September 29. This will probably be the last meeting under the above title, as the Association's purpose will be enlarged and its constitution revised at Springfield. President Vincent T. Williams, of Kansas City, Mo., Editor, *Jackson County Medical Society Weekly Bulletin*, will preside. In the afternoon, Dr. Morris Fishbein, Editor, *Journal American Medical Association*, will give a course in medical writing. There will be a fellowship hour, dinner and speakers in the

In Memoriam

FRANK J. ANDERSON

Dr. Frank J. Anderson, of Minneapolis, died June 25, 1948, at the age of fifty-eight.

Dr. Anderson was born at Ellsworth, Wisconsin, March 29, 1890. He received his medical degree at the University of Minnesota in 1917 and interned at the Minneapolis General Hospital. Postgraduate work in x-ray diagnosis was taken in Chicago and Washington. He served in World War I, from 1917 to 1920, when he began practice in Minneapolis. He had been in charge of the X-Ray Department at Deaconess Hospital, Minneapolis, since 1921.

He was a member of Hennepin County Medical Society, the Minnesota State and American Medical Associations. He also served in World War II and was a member of the Navy-Marine post of the American Legion and the Halverson Bowers post of Veterans of Foreign Wars.

Dr. Anderson is survived by his widow, two sons, Dr. Frank J. Anderson, Jr., and Robert L. Anderson, and two brothers, Alfred and Oscar W. Anderson, all of Minneapolis.

LUTHARD N. BERGH

Dr. L. N. Bergh, a practitioner at Montevideo, Minnesota, for about forty years, died suddenly of a heart attack on June 2, 1948.

Dr. Bergh was born in Yellow Medicine County, Minnesota, on September 27, 1880. He acquired a B.A. degree from Augsburg College, Minneapolis, in 1902, and an M.D. degree from the University of Minnesota in 1906. He interned at the Ancker Hospital, Saint Paul.

He was Division Surgeon for the Chicago, Milwaukee and Saint Paul Railway, a member of the Camp Release County Society, the Minnesota State and American Medical Associations, and was prominent in the affairs of his community.

Dr. Bergh is survived by his widow, a son, Dr. George Bergh, and a daughter, Dr. Solveig Bergh, and two grandchildren, all of Minneapolis.

DANIEL BENJAMIN MARK

Dr. D. B. Mark, son of the late Dr. Joseph Mark, a pioneer Minneapolis physician, died on July 4, 1948, after practicing in Minneapolis for thirty-four years.

Born in Saint Paul, July 16, 1886, Dr. Mark received his medical degree from Barnes Medical College, Saint Louis, Missouri, *summa cum laude,* in 1909. He interned at Asbury Hospital, Minneapolis, and took postgraduate work at the University of Minnesota in 1912.

He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations, the American Academy of General Practice, the American College of Physicians and Surgeons, and a Fellow of the International College of Surgeons. He was a staff member of Asbury and Eitel Hospitals. He was also a Mason, a charter member of the Standard Club and a board member of Adath Jeshurun Cemetery Association.

Dr. Mark is survived by his wife, a son, Dr. Vernon Hershel Mark of Minneapolis, and a sister, Mrs. Henry Crain of Mobile, Alabama.

ARTHUR E. NICHOLS

Dr. Arthur E. Nichols, for many years a practitioner in Saint Paul, passed away March 20, 1948, at the age of eighty-three. He had been Deputy Health Commissioner from 1921 until his death. Dr. Nichols was born in Salem Township, Olmsted County, Minnesota, on December 15, 1864. Preliminary education was obtained at Fergus Falls.

After having been Assistant Postmaster in Fergus Falls for a number of years, he moved to Winnipeg, where he attended Manitoba Medical College for three years. He then went to Chicago, where he graduated from Bennett Medical College in 1900. Internship was served at Cook County Hospital in Chicago.

In 1901 Dr. Nichols came to Saint Paul, where he has practiced since, serving as Deputy Coroner for one year, Director of Hygiene in the public schools for a year, Medical Inspector in the Health Department for two years, and Deputy Health Commissioner from 1921 to the time of his death.

He was a member of the Ramsey County Medical Society, the Minnesota State and American Medical Associations; he was a member of the Masonic Order and a communicant of Saint Clements Episcopal Church.

Dr. Nichols was married January 9, 1901, to Emily Wagner. He is survived by his widow and seven children, John T. Nichols of Baltimore, George Nichols of Los Angeles, Mrs. James Lee Ryan of Springfield, Missouri, Mrs. Conrad Nordquist of Minneapolis, Mrs. John D. Vars, Mrs. E. G. Nattrass and Janet Nichols, all of Saint Paul.

Dr. Nichols was unassuming and retiring by nature, but he maintained the respect and affections of his many lay and professional friends.

EUBERT V. SIMONS

Dr. Eubert V. Simons of Spring Valley, Minnesota, died May 28, 1948, at the age of seventy-four.

Dr. Simons was born April 26, 1874, in Sparta, Michigan. He was a graduate of the Medical and Surgical school of Keokuk, Iowa. Following his graduation in 1903, he practiced in Etna until 1914, when he moved to Spring Valley. With Dr. Cyrus Eby, he operated a hospital in Spring Valley from 1916 to 1925.

He was a member of the Olmsted-Houston-Fillmore-Dodge County Medical Society, the Minnesota State and American Medical Associations.

Dr. Simons is survived by his widow, the former Neva Postle, and one son, Captain Lyle Simons of Fort Sheridan, Illinois. A second son, Fred, died in 1921.

WITH MAY-O-LITE . . .

you never have eyes in the back of your head!

Recently a Minnesotan who works in a large manufacturing plant complained of eye strain. His office desk was arranged so that the windows were at his back, thereby eliminating the extreme light from the southern exposure. However, venetian blinds on the windows reflected in his glasses. Not only was it a strain upon his eyes, but it was bothersome. Quite often he even found himself counting the slats of the blinds. It was as if he had eyes in the back of his head.

The next time his glasses were changed, he had them coated with MAY-O-LITE. Today, he says, "I don't have any more slat trouble."

When objects behind you reflect in your glasses it causes additional eye strain, tends to make you nervous and irritable.

MAY-O-LITE is a scientific method of cutting down annoying surface reflections on your glasses. With MAY-O-LITE, the reflections are reduced from 80 to 95%, eye strain is minimized and lenses become far more resistant to scratches.

MAY-O-LITE Low Reflection Lens Coating is available through your manufacturing and dispending optician. Write for a descriptive pamphlet and a treated sample of glass, today.

New Ulm. Dr. Anderson is maintaining office hours in Lamberton on Saturday afternoons and several evenings each week.

* * *

Announcement was made early in June that Dr. Wesley Spink, professor of medicine at the University of Minnesota, had been appointed to the board of governors of the American College of Physicians.

* * *

A free tuberculosis-examination clinic was held in South Saint Paul on July 8 under the supervision of Dr. Karl Pfuetze, superintendent of Mineral Springs Sanatorium.

* * *

In June, Dr. W. H. Sutherland, Benson, became the president of the Swift County Public Health Association, replacing Dr. C. L. Scofield who had resigned because of ill health.

* * *

Dr. M. M. Hargraves, Rochester, is one of twenty-eight Minnesota residents listed by the Minnesota Historical Society as available as speakers at centennial celebrations in Minnesota next year.

* * *

Dr. Henry E. Michelson, Minneapolis, has been invited to be a guest speaker at a meeting of the Michigan State Medical Society in Detroit on September 22. He also has been invited to address the Indiana State Medical Association at a meeting in Indianapolis on October 25.

After completing his military service on June 16, Dr. R. F. Deranleau became associated in practice with Dr. Paul N. Larson and Dr. William B. Stromme in the Medical Arts Building, Minneapolis.

* * *

It was announced early in June that Dr. Harold Henry, brother of Dr. C. J. Henry and Dr. J. E. Henry of Milaca, was planning to locate in Hinckley to replace Dr. C. G. Kelsey who intended to retire in July.

* * *

During the middle of June, Dr. J. C. Klein, Shakopee, flew to Chicago to attend the annual meeting of the American Geriatrics Association which was held for three days in that city.

* * *

Dr. Robert N. Barr has succeeded Dr. Viktor O. Wilson as chief of the section of special services of the Minnesota Department of Health. Dr. Barr was formerly chief of the section of departmental administration. Dr. Wilson is now city health officer in Rochester.

* * *

Dr. M. C. Petersen, superintendent of the Rochester State Hospital, flew to Europe in June to visit relatives in Denmark, his birthplace, and to inspect mental hospitals in the Scandinavian countries and in Switzerland.

* * *

Dr. S. A. Slater, who has been superintendent of the Southwestern Minnesota Sanatorium in Worthington for the past thirty years, recently was re-elected to the

board of the National Tuberculosis Association for another two-year term. He has been a director of the organization for twenty years.

* * *

Dr. William A. Butcher, formerly of Downey, Illinois, arrived in Stewartville in June to spend six months in association with Dr. A. F. Risser. On January 1, 1949, Dr. Butcher will become affiliated with the Mayo Clinic in Rochester.

* * *

Formerly of Archbold, Ohio, Dr. William L. Lorton has become resident physician at Hibbing General Hospital. He succeeds Dr. Walter W. Kelly, who left to open a practice in California. Dr. Lorton is a graduate of the University of Chicago Medical School.

* * *

The Washington County chest x-ray survey, which began on July 22, will continue through September 30, with headquarters in the armory at Stillwater. In charge of the survey is Dr. Hilbert Mark, tuberculosis division, Minnesota Department of Health.

* * *

Dr. R. A. MacDonald, Littlefork, was married in Duluth on June 15 to Miss Barbara Bramer, formerly a nurse at St. Luke's Hospital, Duluth. Dr. MacDonald is now associated in medical practice with Dr. R. D. Hanover at Littlefork.

* * *

Two former Mayo Foundation fellows were recently advanced to higher academic positions. Dr. Brown M. Dobyns was made assistant professor of surgery at the Harvard Medical School, and Dr. R. D. Harley was appointed associate professor of ophthalmology at Temple University School of Medicine.

* * *

On July 15, Dr. Marcus A. Keil joined the staff of the Mankato Clinic. A graduate of the University of Iowa in 1940, Dr. Keil interned at Miller Hospital, Saint Paul, before entering the army in 1941. Following his army service, he completed a three-year fellowship in internal medicine at the University of Minnesota.

* * *

A former Sanborn resident, Dr. John Yaeger, who was discharged from military service in July, has become the assistant of Dr. R. J. Cairns in Redwood Falls. Dr. Yaeger will be in Redwood Falls during the absence of Dr. James B. Flynn, who is spending a year at the General Hospital in Louisville, Kentucky.

* * *

During June, Dr. Charles G. Sheppard of Hutchinson traded office space with Dr. R. I. Sheppard, dentist, in a Hutchinson office building. Purpose of the trade was to provide more convenient facilities when Dr. Donald Tatum joined Dr. Charles Sheppard on July 1. Both office suites were completely redecorated in the process.

* * *

Candy suckers were used as bribes to promote cooperation as rural St. Louis County youngsters went through the annual health "roundup" during June. Sponsored by the county health department, the "round-

up" provided complete physical examinations and inoculations for the rural children, with the candy persuader helping to expedite the process.

* * *

Dr. J. A. Broberg, Blue Earth, who practiced medicine in Faribault County for fifty years before his retirement in 1942, celebrated his eighty-sixth birthday anniversary on July 5. A graduate of the University of Michigan in 1892, Dr. Broberg began his practice at the age of thirty, living first in Delavan and later in Blue Earth.

* * *

On July 1, Dr. Adrian H. Bodelson became associated in practice with Dr. H. E. Drill in Hopkins (Minneapolis suburb). A graduate of the University of Minnesota Medical School in 1946, Dr. Bodelson interned at St. Mary's Hospital, Duluth, and served for one year as a resident physician in Abbott Hospital, Minneapolis.

* * *

Announcement has been made that Dr. Leo B. Froke has become associated in practice with Dr. F. C. Westerman in Montgomery. A graduate of North Dakota University and the Bowman Gray Medical School in Winston-Salem, N. C., Dr. Froke served his internship at St. Mary's Hospital, Minneapolis, before enlisting in the army in 1942. After four years of active duty, he was assigned to the Veterans Hospital in St. Cloud, where he remained until discharged from service in June.

Dr. E. O. Nimlos, Stephen, left for the West Coast on June 20 to attend the National Red Cross Conference in San Francisco and to enjoy a vacation trip along the Pacific coastline. During his absence his practice was conducted by his son, Dr. Kenneth O. Nimlos, who was discharged from the army about the middle of June.

* * *

The Oliver Clinic in Graceville acquired a new staff physician during the middle of July when Dr. George Louis Barnett arrived from Sioux Fall, South Dakota, to begin his practice in Graceville. A graduate of Creighton University in Omaha, Nebraska, Dr. Barnett served his internship at St. Joseph's Hospital, Omaha.

* * *

Among Minnesota physicians who attended the sixth biennial continuation course in otolaryngology at the University of Minnesota June 28 through July 2, were Dr. R. H. Monahan, International Falls; Dr. John H. Cameron, Crookston; Dr. Joseph L. Arko and Dr. Andrew Sinamark, Hibbing; Dr. Joseph B. Gaida, St. Cloud, and Dr. J. Donald Sjoding, Mankato.

* * *

Announcements of changes in office addresses were recently made by four Minneapolis physicians. Dr. Wilfred J. Bushard is now located at 1750 Medical Arts Building, Dr. Dale H. Correa is at 612 Medical Arts Building, Dr. Roy A. Hoffman is at 2802 E. Forty-

"Let's Talk About Health," the regular health broadcasts of Dr. Donald A. Dukelow over Station KUOM, can be heard each Monday at 11:15 a.m. This new broadcast time became effective August 2. The broadcasts are sponsored by the Community Chest and Council of Hennepin County and by the University of Minnesota. Dr. Dukelow discusses both personal and community health.

* * *

Dr. John P. Dahlstet, formerly of Saint Paul, opened offices for the practice of medicine in North Mankato early in July. He planned to conduct a general practice with some specialization in internal medicine.

A graduate of the University of Nebraska Medical School in 1943, Dr. Dahlstet served an internship and residency at Miller Hospital, Saint Paul. For the past two years he was associated in practice with Dr. J. N. Gehlen, Saint Paul.

* * *

Dr. William T. Peyton, director of the division of neurosurgery in the University of Minnesota Medical School, was a speaker at the International Congress of Psychosurgery in Lisbon, Portugal, on August 6. He spoke on the subject, "Lobectomy in Schizophrenia."

A week earlier, in Paris, Dr. Peyton addressed the staff of the Hospital de la Salpetriere, speaking on "Fluorescein, Di-iodo-fluorescein and Its Isotopes in the Diagnosis of Brain Tumor."

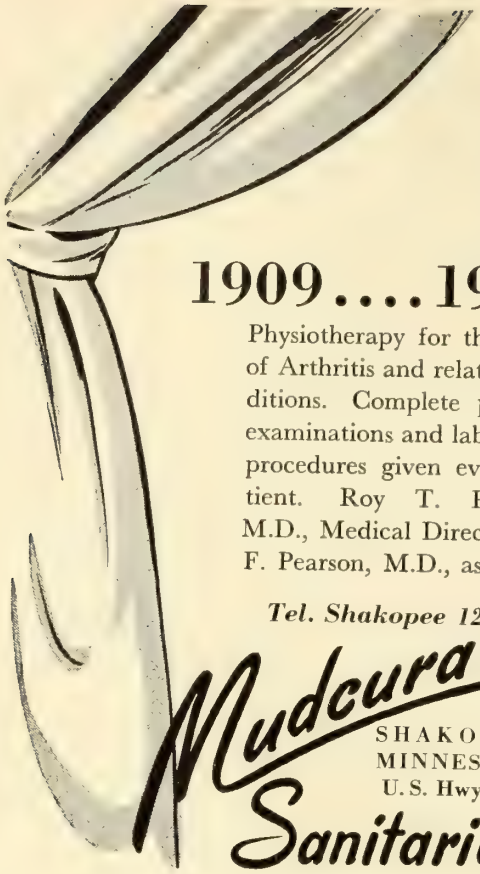
After hoping for twenty years to make the journey, Dr. Swan Ericson and his family left Le Sueur on June 4 for a two-and-one-half-month trip through Sweden. Dr. Ericson came to the United States from Sweden in 1908 at the age of nineteen, unable to speak English. By 1919 he had graduated from the University of Minnesota Medical School. He has practiced at Le Sueur since 1922, hoping to return some day to Sweden to visit his relatives. This summer he achieved that goal.

* * *

Dr. Joseph L. Whelan, Minneapolis, was married on June 12 to Miss Gloria Ann Rewaldt of Gross Pointe Farms, Michigan. The wedding took place in Detroit. A former resident of Chisholm and a graduate of the University of Minnesota Medical School, Dr. Whelan has served for three years in the Army Air Forces and has taken postgraduate work at the University of Pennsylvania Hospital and at Wayne University College of Medicine. At present he is on the resident staff of the University of Minnesota Hospitals and the Veterans Hospital, Minneapolis.

* * *



On July 17, Dr. Wesley W. Spink, professor of medicine at the University of Minnesota, flew to Mexico City to survey the brucellosis problem in Mexico and to help set up a model center for the treatment of human brucellosis by the recently developed streptomycin-sulfadiazine method. Working with Dr. M. Ruiz Castaneda, director of brucellosis control for Mexico's Department of Health, Dr. Spink planned to try the new treatment on 100 of the most difficult cases of brucellosis melitensis available. The project was under the auspices of the National Research Council and the National Institute of Health.

Dr. Spink has been invited to discuss the streptomycin-sulfadiazine treatment, which was developed at the University of Minnesota, at a meeting of Central and South American physicians in Cordoba, Argentina, late in November.

* * *

A medical symposium highlighted the program of the Eighth District Federation of Women's Clubs at a meeting in Buhl on June 29. With the theme, "A Healthier Tomorrow," five physicians presented talks on various phases of medicine. The program, which was arranged by the Minnesota Public Health Association, was as follows:

Dr. Mario Fischer, Duluth, presided and also spoke on "A New Day in Tuberculosis Control." Dr. Earl Barrett, Duluth, presented "Health of the Preschool and School Child," and Dr. Clarence Jacobson, Chisholm, discussed "Contagious Diseases—Then and Now." Dr. Frank Hirschboeck, Duluth, described "New Medical Discoveries," and Dr. E. L. Tuohy, Duluth, spoke on "Geriatrics or Treating of the Aged Population."

BLUE SHIELD NEWS

No. persons covered by Blue Shield as of July 15, 1948	30,000
No. Blue Shield cases paid on July 15, 1948	272
Total for 1948	825
Amount paid on Blue Shield cases on July 15, 1948	$ 9,687.23
Total for 1948	$30,173.39

Recently the Blue Shield office has received many requests from physicians throughout the state for Medical Service Report forms to report cases on *hospitalized patients*. As a result of these requests we would like to explain our reason for not complying.

At the present time a Blue Shield claim is originated in one of the two ways:

1. If the Blue Shield subscriber is hospitalized, the claim is originated from the Blue Cross hospital admission notice.
2. If the Blue Shield subscriber receives Blue Shield services outside of the hospital, the claim is to be originated by the attending physician on a form provided him for that purpose.

Now to go into detail:

When a Blue Shield, Blue Cross subscriber is admitted to a hospital, that hospital sends an admission notice to the Blue Cross office, and a copy of this notice is sent to the Blue Shield office. From this notice the Blue Shield office can start the claim as all the information necessary is on it: the patient's name, name of hospital, physician's name, date of admission, admission diagnosis, etc. This information is transcribed onto a Medical Service Report form that is sent to the attending physician for his completion. This method is used because by the Blue Shield office's completing the form, with the exception of the diagnosis, service and date of discharge from the hospital, the amount of book work on the part of the physician is reduced. Also, this method speeds up the paying of Blue Shield cases for in many instances the hospital report is in before the physician would have a chance to send this office the information.

The case for the Blue Shield subscriber that is treated out of the hospital must be originated by the physi-

ian on a Home and Office Medical Service Report form. This form requires more filling out because only the ubscriber and physician have the information this office eeds. Please do not complete a Home and Office, Medial Service Report form when the patient is hospitalized, or it will mean that we have probably sent out a form overing that hospitalization, and thus duplicate work s done.

This article is taken in part from the Manual that vas sent to all participating Doctors of Medicine. For urther details on handling claims the reader is referred o the above-mentioned Manual.

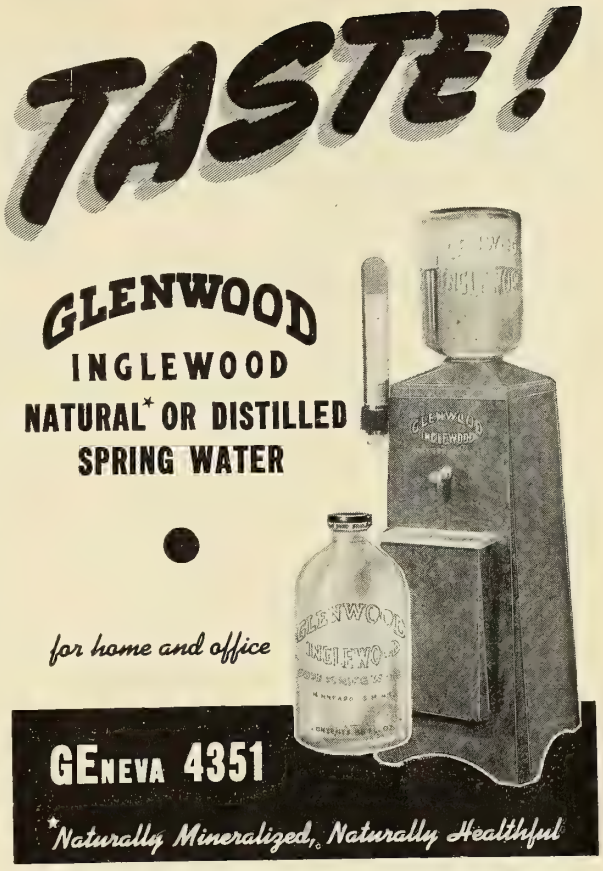
DISTRICT HEALTH OFFICES

The entire state of Minnesota is now supplied with district offices of the State Department of Health. The wo newest districts, Numbers 7 and 8, were opened during July. Headquarters for District 7 are at Fergus Falls and for District 8 at Little Falls.

Dr. E. J. Simons of Swanville has been appointed half-time health officer and director for District No. 8. As yet no health officer has been found available for District No. 7. Mr. Frederick F. Heisel, public health engineer, is temporarily in charge of that district.

Following are the directors, counties included, and headquarters for each public health district:

District 1.—Director, Dr. George Miners, Bemidji; counties included: Beltrami, upper Cass, Clearwater, Hubbard, Itasca, Kittson, Koochiching, Lake of the Woods, Mahnomen, Marshall, Pennington, Polk, Red Lake and Roseau; headquarters in Court House, Bemidji.



District 2.—Director, Dr. A. G. Liedloff, Mankato; counties included: Blue Earth, Brown, Carver, Faribault, Le Sueur, Martin, McLeod, Nicollet, Scott, Sibley, Waseca, Watonwan; headquarters, Court House, Mankato.

District 3.—Acting director, Dr. V. O. Wilson, Rochester; counties included: Dodge, Fillmore, Freeborn, Goodhue, Houston, Mower, Olmsted, Rice, Steele, Wabasha, Winona; headquarters, Room 212, City Hall, Rochester.

District 4.—Acting director, Dr. Mario McC. Fischer, Duluth; counties included: Aitkin, Carlton, Cook, Lake, Pine, St. Louis; headquarters, Room 115, Court House, Duluth 2.

District 5.—Acting director, Dr. B. O. Mork, Jr., Worthington; counties included: Chippewa, Cottonwood, Jackson, Lac qui Parle, Lincoln, Lyon, Murray, Nobles, Pipestone, Redwood, Renville, Rock, Yellow Medicine; headquarters, Court House, Worthington.

District 6.—Director, Dr. A. B. Rosenfield, Minneapolis; counties included: Anoka, Chisago, Dakota, rural Hennepin, Isanti, Kanabec, rural Ramsey, Washington, Wright; headquarters, State Board of Health Building, University Campus, Minneapolis 14.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

PRACTICE OF ALLERGY. Second Edition. Warren T. Vaughan, M.D., Richmond, Va. Revised by J. Harvey Black, M.D., Dallas, Texas. 1132 pages. Illus. Price $15.00, cloth. St. Louis: C. V. Mosby Co., 1948.

PRINCIPLES GOVERNING EYE OPERATING ROOM PROCEDURES. Emma I. Clevenger, R.N. Supervisor, Eye Operating Room, New York Eye and Ear Infirmary, New York City. 215 pages. Illus. Price $5.50, cloth. St. Louis: C. V. Mosby Co., 1948.

MR. PRESIDENT—HOW IS YOUR HEALTH? Karl C. Wold, M.D., Saint Paul and Minneapolis: Bruce Publishing Company, 1948. Price $3.00.

To anyone, physician or layman, who has even a small amount of interest in history, this comparatively small volume of 214 pages, written by Dr. K. C. Wold, a well-known oculist of Saint Paul, will prove interesting reading.

The volume represents many hours of research, and the assembling of material has been the author's main hobby for a number of years. He has avoided the use of unnecessary medical or technical terms, or has explained those used, so that the text is fully understandable for the non-medical reader. It should appeal to the laity as well as those interested in medicine and allied fields.

SYNOPSIS OF NEUROPSYCHIATRY. Lowell S. Selling, M.D., Ph.D., D.P.H., F.A.C.P. 561 pages. Illus. Price $6.50. St. Louis: The C. V. Mosby Co., 1947.

This is the second edition of Dr. Selling's book which outlines in a brief but helpful manner the various, most common neuropsychiatric disorders. Though of necessity brief, it considers the various syndromes and symptom complexes in an orderly fashion.

The section on neurology reviews the basic anatomy of the nervous system by way of foundation for the later consideration of neurological diseases which are divided into conditions affecting (1) the peripheral nervous structures, (2) the spinal cord, (3) the brain stem, (4) the cranial nerves, (5) the cerebellum, (6) the cerebrum, (7) the meninges, (8) the antonomic and sympathetic nervous system, (9) a chapter dealing with disorders of symbol use, which is an additional chapter in this edition describing disorders of speech and expression, (10) the convulsive states and (11) muscle syndromes.

The section on mental disorders discusses Basic Principles, the General Etiology of Mental Diseases, Symptomatology of Mental Disease, Neurosyphilis, Alcoholism, Drug Addiction, the Psychoses, the Psychoneuroses, Psychopathic Personality, Psychosomatic Medicine, Behavior Disorders of Childhood, and Mental Deficiency.

The chapter on psychiatric treatment is one of the best, in that it follows no one school but attempts to consider therapy from an over-all viewpoint, giving fair consideration to the psychoanalytic, psychobiologic and physiologic schools of psychiatry.

This is an excellent book for the student and general physician. It will be a time-saver for the specialist in the field. It has a well-chosen reference bibliography.

L. R. GOWAN, M.D.

Medicus *— writing in the Minneapolis Star of July 8 — says,

"The hospitals and their staffs are much to blame for the present shortage of applicants for nurses' training.

"Many nursing schools require that an applicant have a college degree before becoming even a probationer in a hospital. Thousands of qualified young women are thus shut off from carrying out a lifetime ambition."

GLENWOOD HILLS HOSPITALS PIONEERED in the other direction. For some years we have offered a one-year course in **modern methods, modern nursing, modern patient care** to **young women with high school education.**

They are capable of appreciating the needs of that important person the patient, giving him the right attention and the right food to make him comfortable.

Thanks to you registered physicians, our midsummer class was oversubscribed. We are now enrolling for the September class in the

SCHOOL OF PSYCHIATRIC NURSING

Our graduates are the ones most desired by doctors and clinics. . . . They are well trained, loyal, eager to serve.

Doctors who operate their own hospitals in smaller communities seek our graduates.

The most capable of these graduates are the ones who come doctor-recommended.

We appreciate the cooperation rendered by you doctors

**Medicus is the pen name of a prominent Minnesota physician.*

Nominate some young woman for the course.
We will send you and her our booklet.

recognition. No carbohydrate employed in this system of infant feeding enjoys so
rich and enduring a background of authoritative clinical experience as Dextri-Maltose.

DILANTIN

denotes defense

against the grand mal or psychomotor type of epileptic seizure. In the majority of patients, DILANTIN prevents attacks or greatly decreases their frequency or severity. Optimal control is afforded by individualized dosage determined by trial in the particular case. Relative freedom from hypnotic side-effects enhances the effectiveness of DILANTIN in fostering the patient's return to his normal activities.

DILANTIN Sodium (diphenylhydantoin sodium, P. D. & Co.) is available in 0.03 gm. (½ gr.) and 0.1 gm. (1½ gr.) Kapseals,® in bottles of 100 and 1000.

middle age + pleasurable living

Perhaps, at no other time does a woman need reassurance so much as during the trying period of the menopause when physical and emotional instability threaten her feeling of security.

Equanimity of spirit and body may often be restored with **"Premarin."** *This naturally occurring, orally active estrogen offers many advantages but undoubtedly one of the most gratifying effects of therapy is the "sense of well-being" usually expressed by the patient...the "plus" in* **"Premarin"** *which gives the woman in the climacterium a new lease on pleasurable living.*

To adapt estrogen treatment to the individual needs of the patient three **"Premarin"** *dosage forms are available: tablets of 2.5 mg., 1.25 mg. and 0.625 mg.; also liquid 0.625 mg. in each 4 cc. (1 teaspoonful).*

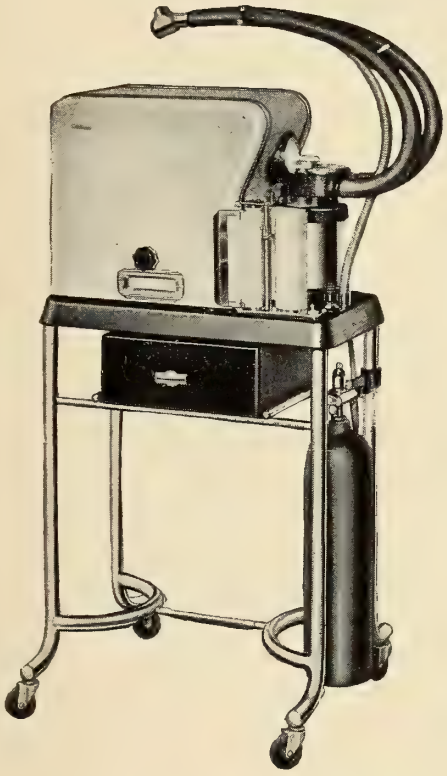
While sodium estrone sulfate is the principal estrogen in **"Premarin,"** *other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water soluble conjugates.*

* **CONJUGATED ESTROGENS (equine)** **"PREMARIN"®**

Ayerst, McKenna & Harrison Limited 22 East 40th Street, New York 16, New York

*Estrogenic Substances (water soluble) *also known as* Conjugated Estrogens (equine)

Yet, **Henry's *never* hungry for dinner**



Henry's habit of "nibbling". . . the quantities of pop and red-hots, tamales and ale and fish and chips that he wraps himself 'round in a year's time . . . deadens his appetite for more balanced fare. And just as surely as if he were a diet faddist, a hurrier, a worrier, Henry is rapidly approaching that half-sick, half-well feeling so indicative of subclinical vitamin deficiency. You know these cases call for dietary reform. But you know, too, how hard it is for people to stay on a proper diet. That's why many physicians rely on vitamin supplementation. When this is indicated in your own practice, remember the name, Abbott—a leader in vitamin research and development. There's an Abbott vitamin product to answer your patients' needs for single or multiple vitamins, for supplementary or therapeutic levels of dosage, for oral or parenteral administration. They are rigidly standardized for the contained vitamins. Available at prescription pharmacies everywhere. ABBOTT LABORATORIES, North Chicago, Illinois.

Urinary Stimulation

Stimulation of urinary secretion with Salyrgan-Theophylline appears to be due chiefly to its renal action consisting of depression of tubular reabsorption. In addition, there is a direct influence on edematous tissue, mobilizing sodium chloride and water.

Salyrgan-Theophylline is indicated primarily in congestive heart failure when edema and dyspnea persist after rest and adequate digitalization. Gratifying diuresis usually sets in promptly and often totals from 3000 to 4000 cc. in twenty-four hours.

Injections at about weekly intervals help to insure circulatory balance for long periods of time.

Good results may also be obtained in chronic nephritis and nephrosis.

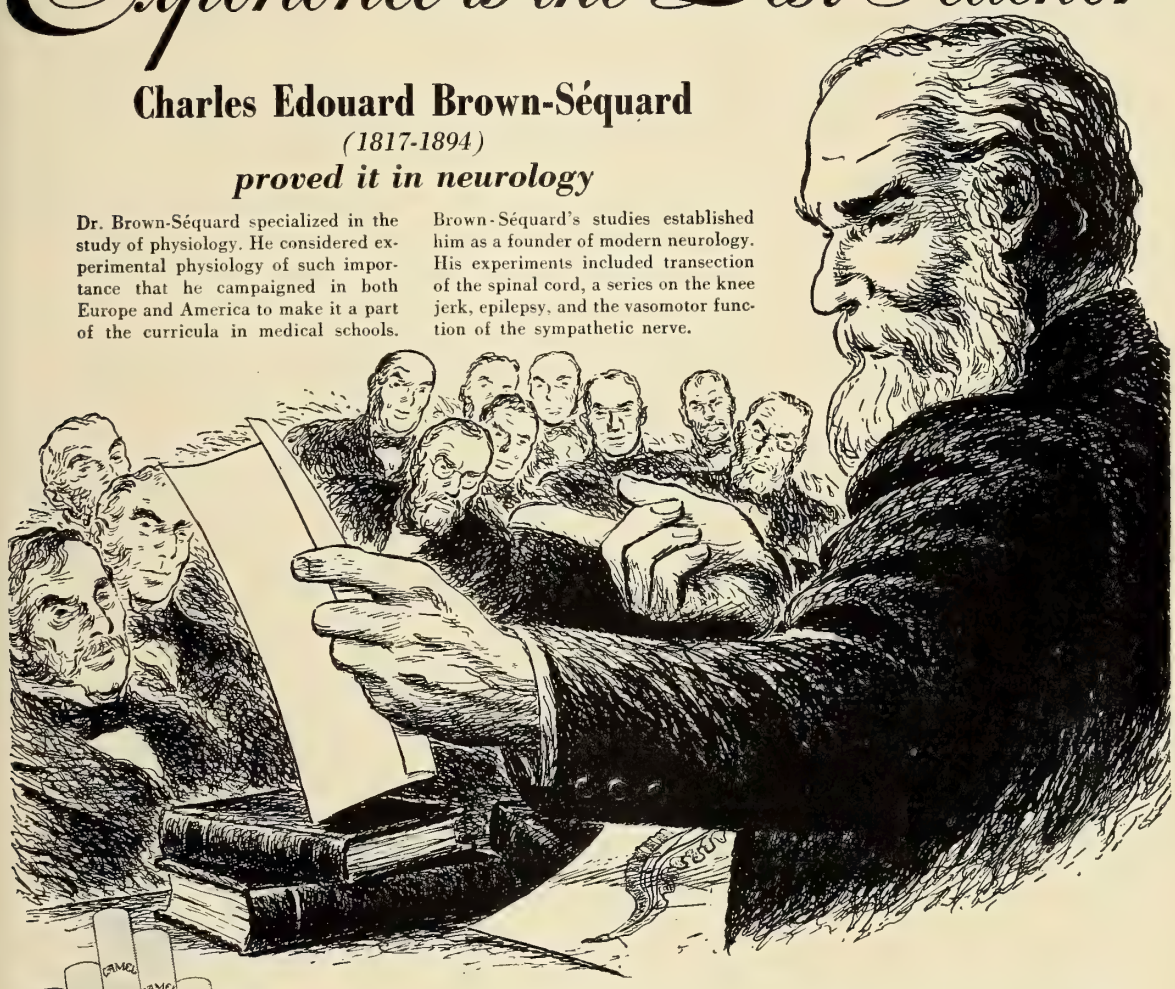
Experience is the Best Teacher



Charles Edouard Brown-Séquard

(1817-1894)

proved it in neurology

Dr. Brown-Séquard specialized in the study of physiology. He considered experimental physiology of such importance that he campaigned in both Europe and America to make it a part of the curricula in medical schools.

Brown-Séquard's studies established him as a founder of modern neurology. His experiments included transection of the spinal cord, a series on the knee jerk, epilepsy, and the vasomotor function of the sympathetic nerve.

Experience is the best teacher in cigarettes, too

YES! Experience counts. Millions of smokers who have tried and compared many different brands of cigarettes found from experience that Camels suit them best. As a result, more people are smoking Camels than ever before.

Try Camels! See how *your* taste appreciates the rich, full flavor of Camel's choice, properly aged, and expertly blended tobaccos. See if *your* throat doesn't welcome Camel's cool mildness.

Find out for yourself why, with millions of smokers, Camels are the "choice of experience."

R. J. Reynolds Tobacco Co.
Winston-Salem, N.C.

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS

than any other cigarette

Three independent research organizations in a nationwide survey asked 113,597 doctors to name the cigarette they smoked. More doctors named Camel than any other brand.

MEAT...

And the Nutritional Significance of Fat

The all too prevalent practice of trimming the fat from many meat cuts and discarding it not only represents unnecessary economic, but also nutritional, waste. Fat is nutritionally valuable for several reasons, some of them well known, some only recently appreciated.

The fat of meat is an outstanding source of caloric food energy, small in bulk and low in moisture. It carries important fat-soluble vitamins, is well digested and absorbed, and endows the meal with satiety value making for real satisfaction. Meat fat furthermore contains certain unsaturated fatty acids which appear to play a significant and essential part in skin metabolism. Fat also exerts a sparing effect with regard to B complex vitamins.

Recent evidence[1,2] indicates that the presence of fat in a mixed dietary considerably decreases the specific dynamic effect of the three basic nutrients, thus promoting optimal utilization of the protein ingested.

This survey of the nutritional significance of fat again emphasizes the valuable role of meat fat in the daily dietary.

In the Conservative Treatment of

The Lumbosacral and Lower Lumbar Regions

CAMP SUPPORTS offer advantages

...Give firm support to the low back; the support is easily intensified by re-inforcement with pliable steels or the Camp Spinal Brace.

...Afford a more stable pelvis to receive the superincumbent load.

...Allow freedom for contraction of abdominal muscles under the support in instances of increased lumbar curve (fig. 1).

...Are removed easily for prescribed exercises and other physical procedures prescribed by physiatrist or physician.

FIGURE 1 — Patient — thin type of build with beginning faulty body mechanics. The Camp adjustment provides a more stable pelvis, allowing patient to "draw in" the abdominal muscles thus gradually acquiring a gentle lumbar curve.

FIGURE 2 — Patient — intermediate type of build. Strain of lumbosacral joint predisposes to other strains. For protection of the joints in the lumbar region from recurrent strain and also as an aid in relieving the pain of acute conditions, Camp lumbosacral supports have proved effective.

for liver damage **MEONINE®**

(dl-methionine Wyeth)

IMPORTANT WYETH ADDITION TO

New and Nonofficial Remedies

Realizing that traditional management of severe liver disease has been on the whole disheartening, Wyeth has for years been conducting research on the essential amino acid most concerned with liver function . . . dl-methionine.

Product of this research is Meonine.

Meonine may be used to supplement the protein-rich diet usually prescribed whenever the liver has been damaged by malnutrition, alcoholism, pregnancy, allergy, or toxins. And it is clearly indicated if this diet cannot be taken. There is no evidence, however, that Meonine is more effective than foodstuffs such as casein and egg white which contain pure methionine.

In early stages of cirrhosis, clinical results with Meonine have been most encouraging. Complete directions for use and bibliography supplied on request.

Meonine supplied in 0.5 gram tablets, bottles of 100 and 1000. Crystalline Meonine—for preparing injection solutions—supplied in 50 gram bottles.

Wyeth®

THE HIGH-PROTEIN INFANT FOOD

The incidence of mild protein deficiencies in children, predisposing toward infections and edema, is reported[1,2] much greater than generally realized. Infant and adolescent requirements—not only for tissue repair and maintenance, but also for growth—are much higher than in adulthood.[3] To insure adequate protein intake in infancy, DRYCO—Borden's high-protein infant food—is ideally suited as a basis for formula building. It furnishes *all the essential amino acids.* Its low fat content minimizes gastro-intestinal upsets due to fat intolerance, while its intermediate carbohydrate content lends itself for prescription with or without added carbohydrate. Quickly soluble in cold or warm water, DRYCO contains adequate vitamins A, B_1, B_2 and D, plus essential milk minerals.

The First Bacteriology...

Medicine and Dentistry honor Louis Pasteur (1822-1895) and Robert Koch (1843-1910) as the co-founders of bacteriological science.

Pasteur proved that certain micro-organisms present in the air caused the fermentation of milk, wine and beer . . . that certain animal diseases were spread by still other bacteria. His reports stimulated valuable research into the new science by others—notably Lord Lister, who grasped their significance for surgery and introduced sterilization to the operating table in 1865.

Koch, the young German physician whose fancy turned to germ-study when his wife gave him a microscope for his birthday, developed an accurate and scientific method for the separation of pure cultures of disease-bacteria, and for their use in animal inoculation. Discovery of the germs of the more common diseases, and protective measures against them, were rapid after 1880.

Doctors Since 1899 also have been gratified by the rapid development of protective measures against malpractice claims and lawsuits. The Medical Protective policy offers *complete* protection, *preventive* counsel and *confidential* service.

MAY-O-LITE Helps Your Patients . . . Enjoy Their Glasses

If glasses are prescribed, they should be worn. However, often glasses are laid aside and not worn because of some hard to explain "bother," which is in most cases reflection on the lenses.

Recently, a high school girl was fitted with her first pair of glasses. After a few days, she laid them aside because they didn't seem right . . . they "bothered" her. Later, when she told her doctor that she could "see things" in them, he suggested May-O-Lite coating. Not long after that the young lady called him on the phone, exclaiming, "Now I can wear my glasses anywhere, in school, on the street . . . and those 'things' just aren't there."

MAY-O-LITE Low Reflection Lens Treatment reduces surface reflection from 80 to 95%.

Besides reducing surface reflection and minimizing eye strain, MAY-O-LITE improves image definition. MAY-O-LITE Low Reflection Lens Coating is available through your manufacturing and dispensing optician. Write for a descriptive pamphlet and a treated sample of glass, today.

NATIONAL HEALTH LEGISLATION

SENATOR JOSEPH H. BALL
Saint Paul, Minnesota

FOR the sake of clarity and brevity, I have divided my subject into three parts:

1. What the federal government is now doing in the health field.
2. Pending legislation proposing additional federal activities and its prospects for enactment.
3. My own views as to the development of a sound federal health program.

What the Federal Government Is Now Doing in the Health Field

As most of you here know, activities of the federal government in the field of health have increased tremendously in the past few years. As a member of the Appropriations Subcommittee which handles the Federal Security Agency appropriation bill, I have watched that growth during the past four years.

The appropriation bill for the fiscal year beginning July 1, 1948, and ending June 30, 1949, is still in conference between the House and Senate, but only a few minor items in the health program are in controversy, so we know substantially what the federal program in this field is for the fiscal year of 1949. That program, including the grants to assist hospital construction, totals $184,380,000. Of that total more than $133,000,000 is for grants to states and local communities and research centers at universities and hospitals, while the federal government will spend directly a little over $51,000,000.

The appropriation for research and treatment of venereal diseases totals $17,230,000, of which $13,323,000 is for grants to state and local communities, some of it for the rapid treatment centers, and another large sum for various state services in this field.

Next year's appropriation in the field of tuberculosis totals $9,291,000, of which $6,790,000 goes in grants to state and local communities and to various research centers. In addition, the federal government spends much of its $2,500,000 for the x-ray projects carried on in some of our larger cities.

The bill carries an appropriation of $14,865,000 for general assistance to states, $12,565,000 of which is for direct grants and the remainder for consultative services. The grants to states under this program go largely to bolster up various public health programs.

The Public Health Service will spend $7,490,000 next year for direct work on communicable diseases, most of it spent in co-operation with the states and local communities on various projects such as the malaria eradication projects in some of the southern states.

The appropriation next year for the National Cancer Institute is $14,000,000, of which $4,150,000 is for research grants to various hospitals and research institutions. In addition the bill carries $8,000,000 of contract authority for grants to research centers for construction of new research facilities for the study of cancer.

For the National Mental Health Institute, next year's appropriation is $10,278,000, of which $8,372,000 again is for research and training grants to state and local communities and research centers, and nearly $4,000,000 for grants to states.

Under the Hill-Burton Hospital Construction

Read before the Public Health Meeting, Minnesota State Medical Association, Minneapolis, Minn., June 9, 1948, by Dr. Reuben F. Erickson, in the absence of Senator Ball.

Act, which provides for $75,000,000 a year of federal assistance in building hospitals over the next five years, the cash appropriation for the next year is $60,000,000 plus $13,000,000 which will be carried over from this year's budget, with an additional contract authorization of $65,000,000.

The 1949 bill also includes $5,000,000 in cash and $25,000,000 of contract authorization for construction of a clinical center and research hospital at Bethesda, Maryland. This project, which is planned for completion by July 1, 1951, is expected to provide adequate laboratory space and also hospital research facilities for clinical research on cancer, heart disease and mental diseases. It is a tremendous program and when completed will cost the federal government between 10 and 15 million dollars a year to operate.

I have not included in these figures the same $25,000,000 which the Public Health Service spends annually in operating marine hospitals and the foreign quarantine service, because these are not the sort of public health programs that we are talking about here today.

However, these totals, while they may seem relatively small in comparison to the billions that we are appropriating for national defense and foreign assistance, nevertheless constitute a very large federal health program. It is a program that is being expanded, particularly in the field of research, as rapidly as trained research personnel are available to carry on an expanded program. I think it is an especially sound program in that the bulk of the federal funds expended on research and public health projects by the federal government are not spent directly, but are grants to state and local communities and to research institutions scattered throughout the country. I am convinced that such a decentralization leads to a much sounder and more effective program than to have the federal government undertake this work directly.

There have been a number of proposals in recent years for the federal government to appropriate huge sums, tens or even hundreds of millions of dollars to mobilize the scientific world for a blitzkrieg attack, so to speak, on some particular disease. This has been particularly true of cancer. The Congress, wisely, I believe, has resisted the pressure for such haphazard and unco-ordinated attacks on the health problems of the nation. The fact is that there are not available either the research facilities or the trained research personnel to undertake that kind of a program, even if it were sound to do so. Instead of that, working largely through the appropriation committee, we have expanded the research programs in all major fields just about as rapidly as the funds could be economically and efficiently spent.

The Hill-Burton Hospital Construction Act, although it was passed more than two years ago, is just beginning to get into operation. The testimony before the appropriations committee indicated that only about $2,000,000 will actually be expended in federal grants during this fiscal year out of $15,000,000 appropriated.

I think the slowness of the hospital program to get under way was due in part to the complexity of the federal regulations in the beginning, plus the fact that all the states were required to develop their own plans before any individual projects could be approved. It is only in the past six months that most of the states have qualified for aid under the program and projects are now being approved in increasing numbers.

Although the tremendously increased costs of construction undoubtedly will cut down the volume of hospital construction under the act, and may necessitate a further extension of the law and some increase in the totals authorized, it nevertheless should contribute very substantially to closing the gap between the need for hospital beds and the facilities now available. Particularly it should assist many smaller rural communities which lack first-class hospital facilities today to build adequate facilities over the next five years.

Pending Legislation Proposing Additional Federal Activities and Its Prospects for Enactment

Coming now to pending legislation in the health field, we confront a rather involved picture. In all, there are eighteen bills dealing with health in the Senate Committee on Labor and Public Welfare, and about an equal number in the House Committee on Education and Labor.

The two bills about which most has been heard are S.545 and S.1320, both dealing with medical care to individuals. S.1320, which you may know as the Wagner-Murray-Dingell bill, proposes a comprehensive, compulsory system of federal medical care insurance under which all employed and self-employed persons would be taxed to create a central health fund. The federal government would operate the entire system and, despite the

disclaimers, the bill if it became law would socialize the practice of medicine in the United States.

S.545, introduced by Senator Taft and several others including myself, on the other hand, is essentially a grant-in-aid bill to assist states and local communities in providing medical and dental care to individuals who are unable to pay the whole cost of such care themselves. The bill is based on the philosophy that all individuals other than the indigent should make their own provisions for medical care. It further would encourage state initiative and experimentation in solving the problems of medical care for the indigent through the development of voluntary prepayment insurance plans such as the Blue Cross and Blue Shield.

Most of the other pending bills either provide for additional federal funds for research in some particular field or for the training of scientific and research personnel or for grants to states for some particular activity. Many of them duplicate provisions of either S.545 or S.1320.

One of them, S.2215, sets up a national heart institute similar to the national cancer institute. That bill has been reported out by the committee and passed by the Senate. It does not actually provide for any activity which the Public Health Service is not carrying on at present under language in its appropriation bills, but it does put research in heart disease on a par with research into cancer and mental diseases.

The committee has also approved, the Senate has passed, and the House probably will pass, the National Science Foundation bill which provides for research and training in all the sciences including medicine.

Outside of those two measures, the National Science Foundation bill and the National Heart Institute bill, both of which are expected to be enacted at this session, it does not appear likely that any other important legislation in this field will be passed this year.

Hearings on the two major bills, S.545 and S.1320, although they have been held intermittently for many months and fill several volumes of printed records, are still incomplete. And in any event, S.1320, the compulsory health insurance bill, does not stand a chance of passage by this Congress.

The whole trend in Congress in the past three years has been away from further experiments in socialization rather than toward them. Furthermore, the report of the Brookings Institution on the whole question of medical care for the individual, made for the Senate Health Subcommittee, has dampened very considerably any enthusiasm that did exist in Congress for rushing into some kind of federal program to provide medical care for individuals.

The Brookings Institution report emphasized very strongly the dangers in that course of action and exploded rather completely the myth so extensively propagandized in recent years that the United States is a nation of weak, unhealthy cripples, ridden by disease and completely lacking in adequate medical care. To anyone who has observed the health of peoples in other countries, including those which have experimented with socialized medicine, it was always apparent that the phony statistics and half-truths of which the propaganda for the Wagner-Murray-Dingell bill was built did not present a true picture of this nation's health position, but it was very helpful to have an impartial research agency like the Brookings Institution confirm that fact.

The Brookings Institution goes further and points out that the progress in health, in longevity and in the control of epidemics in the United States, with its free and voluntary medical system, has been extremely rapid and that wrecking that voluntary system by a compulsory health insurance program probably would mean retrogression rather than progress.

My Own Views as to the Development of a Sound Federal Health Program

And now, finally, where should we go from here in developing a sound federal health program?

Permit me to list briefly, in order of the priority I would assign to them, the measures which I believe the federal government should undertake in this field.

First, let me say that I am convinced that in the tremendous emphasis on medical care for the individual in the past few years, we have tended to lose sight of what should be the major concern of government in the health field, which is a positive rather than a negative approach to health. In other words, instead of developing huge programs to provide medical care for individuals who have contracted disease, we should concentrate on public, private and co-operative programs to build the health of our people in positive terms, to prevent disease rather than cure it after it has oc-

curred. That is a long-established and legitimate field for governmental activity and one which still needs strengthening.

Furthermore, with full employment today and a national income of more than 200 billion dollars, there are relatively few families who cannot afford adequate medical care if they want to give that care the priority it should have in over-all expenditures for the family.

So, in order of priority, here are the things I think Congress should do in the next few years in this field of public health:

First, Congress should try to achieve some co-ordination between the tremendous veterans program in this field and that of the Public Health Service. There is no co-ordination today, and yet the Veterans Administration is spending hundreds of millions of dollars on medical care and potentially may have the major obligation for hospital treatment at least for anywhere from five to ten million veterans within a few years.

In the field of hospital construction, for instance, the Hill-Burton bill provides for a $750,000,000 construction program over five years. The Veterans Administration already has blueprints for a billion-dollar hospital construction program over the next five or ten years. Inevitably, with such a large percentage of our population today being veterans, the construction program for the Veterans Administration will affect tremendously the need for other private and public hospitals in any particular area. And yet today there is no direct co-ordination between the Veterans Administration hospital program and the building programs being developed by the states under the Hill-Burton Act. We have talked a great deal about centralizing health services in one federal agency, but it seems to me that without some real co-ordination between the Veterans Administration and the Public Health Service such centralization will not accomplish much.

Second, the federal government should continue to expand its research and training program, chiefly through the method of grants to state and local communities and research institutions, which will assure decentralization of the activities and prevent the building up of a huge bureaucracy which would stultify rather than strengthen research.

Third, Congress should provide for federal grants to extend standard public health services to those localities and communities which are not financially able to carry the whole burden themselves. A bill, S.2189, introduced late this session, proposed such a program. It is probably too late for proper study before action at this session, but it should be high on the agenda for the next session of Congress.

Fourth, Congress should act on proposals which have been pending for several sessions to provide federal assistance for sewage disposal plants to clean up the pollution which has ruined so many of our fine rivers, and also to strengthen industrial hygiene programs in various states. Again such programs should be carried out through grants to the states providing for decentralized administration.

Fifth, the federal government, when funds are available within a balanced budget, should assist the states in developing and strengthening a program of health education in the public schools, possibly coupled with annual examinations of school children in order that diseases may be diagnosed early enough for effective treatment.

Sixth, as federal funds are available, Congress might provide federal assistance to states to assist in improving medical care for indigent people. Such a program should allow the states wide latitude to adopt their own plans for such care and should encourage the development of such voluntary prepayment plans as the Blue Cross and the Blue Shield systems.

In conclusion, I believe it is much wiser and sounder, in the long run, for us to go a little more slowly in expanding present federal programs and in inaugurating new ones, rather than enthusiastically rushing to spend millions every time some new panacea for the nation's health problems is proposed. If I have learned one thing in eight years in the Senate, it is that quick panaceas for serious and complicated problems are almost inevitably a snare and a delusion. They tend almost always to concentrate ever greater power in the central government, a tendency which carries grave dangers for individual freedom.

And even though some enthusiasts, looking only at the problems in the particular field, may overlook it, there are limits to the resources of the federal government. It can spend only the money it collects from you and me in taxes, and taxes can become so high that they destroy the

(Continued on Page 1015)

TEAMWORK IN THE CONSERVATION OF HUMAN RESOURCES

MORRIS FISHBEIN, M.D.
Chicago, Illinois

LESS than fifty years have passed since the time when medicine was practiced almost wholly by general practitioners with a few specialists, all of whom were concerned primarily with the diagnosis and treatment of disease. Hardly one hundred years have passed since the profession of public health was joined to the professions that render maximum service to mankind.

Today in the United States, where we have reached the highest standard of medical care and perhaps also of preventive medicine that prevails in any great nation in the world, the physician, the public health worker, the social worker, the hospital administrator, the technicians in the field of clinical pathology, sanitary engineering and entomology, the nurses, the dietitians, the record librarians and many others work together in the development of a pattern of medical care suitable to the American way of life. The care of the sick in the United States today is a full-time job not only for the 180,000 physicians who are licensed to practice and who are active in the field but for at least 2,500,000 to 3,000,000 additional people who are concerned with the prevention of disease and the care of the sick. The result of this magnificent teamwork has been the great change in the picture of the medical problem in the United States in the last fifty years.

The contrast with other nations in which similar progress has not been made is striking. In 1900 in the United States tuberculosis was captain of the men of death; today tuberculosis is sixth or seventh in the list of causes of death. The improvement has been brought about by teamwork. Before the team could apply its methods, scientific research had to make available exact knowledge on which action could be based. The determination of the cause of tuberculosis and its method of spread enabled studies of the sputum for the presence of the germ and led to the establishment of sanatoriums in which those who spread the disease could be isolated away from their families. Then came the establishment of some 800 sanatoriums in the United States where the tuberculous are given modern methods of treatment. Subsequently came the development of artificial pneumothorax as a means of putting at rest the diseased lung. Thereafter came the use of the x-ray to detect the lesions in their earliest stages and the use of the tuberculin test for the detection of those susceptible to the disease. Thereafter came the establishment of methods of hygiene and of preventoriums for encouraging the resistance and the safety of little children. In this work the National Tuberculosis Association with its tremendous educational campaigns, financed by the Christmas Seal sale, played a leading role. And now we are in the era of chemotherapy with the use of streptomycin and various derivatives of the sulfonamide drugs as well as the BCG vaccine, with the likelihood, for the first time, that tuberculosis may be made as rare as typhoid fever in the United States in another two generations. The death rates from tuberculosis in the United States have dropped from 270 per 100,000 population to rates below 30 in Minnesota, which is among the leaders in the nation in this work. Elsewhere in the world, there are still death rates from tuberculosis of 250 to 450 per 100,000 population.

Consider how the team has functioned in this attack. Here are the combined efforts of philanthropic associations led by social workers and medical statesmen. Here are the activities of the health authorities—national, state and local—integrated into the national scheme. Here is the work of the individual physician who detects the disease in the patient and cares for him whether that care is rendered in the home, the hospital or the sanatorium. Here are applied the activities of all of the technicians already mentioned and, in addition, the physical therapists, the occupational therapists, the psychologic-social workers and the specialists in rehabilitation.

I have taken the fight against tuberculosis carried on by these organizations as a conspicuous example of medical teamwork for the conservation of human resources, but I could equally well refer to other agencies which are a part of our American scheme. Outstanding has been the contribution of the National Foundation for Infantile Paralysis, the American Heart Association, the

*Abstract of a paper presented at the Public Health Meeting, June 9, 1948, held in Minneapolis in connection with the 95th Annual Meeting of the Minnesota State Medical Associaton.

American Cancer Society, the National Society for Crippled Children and Adults, and special organizations devoted to the blind, to the hard of hearing, to those with multiple sclerosis, epilepsy and similar diseases. These represent the complete co-operation of the medical profession, the great philanthropists, the administrators and social workers organized to function together first in the raising of funds, second in the encouragement of research, third in the care of those who would not receive adequate care otherwise, and fourth in education of the public. These are the chief functions which these great organizations have carried on so magnificently.

The outstanding feature of American medicine is its continuation in the field of what is commonly called private enterprise. But it is the pride of the private enterprise of American medicine that it co-operates with every agency concerned equally in maintaining a high quality of medical care and the highest possible standards in the prevention and control of disease. Let us consider the evolution of our present American system of medical care. Again the service of the family doctor of an earlier day has evolved into a variety of services rendered under a variety of conditions. The general practitioner is still today the functioning unit in most medical care. Upon him devolves the duty of medical counselor for the family—the first to detect disease and the first to give proper care for the vast majority of conditions for which patients consult doctors. He also, however, must determine whether or not the patient requires the services of a hospital or a diagnostic institute. He must decide whether or not he wishes the consultative services of groups of specialists individually or in organized agencies.

In the growth of our hospitals we have a magnificent example of community effort exercised through agencies of the church, of trade organizations and of whole communities. Into this picture comes the government aid manifested by the Hill-Burton Act with the understanding always, however, that the hospital is the health center of a local community upon which must rest the responsibility for its administration and its maintenance. In the hospital the administrative board, the medical staff, the superintendent and a great variety of highly trained technical employes work as a team for the good of the individual patient. Behind the care of every sick patient are dozens of highly trained persons concerned with giving to each of the sick the best that modern medicine can give. In the operating room, in the delivery room, in the diagnostic clinic, always one sees, under the leadership of the physician who assumes the prime responsibility for the rendering of service, the specialist, nurses, interns, assistant residents and residents who are improving in their training, the anesthetist, the roentgenologist, the clinical pathologist and all of the other associates again focusing on the care of one patient the most that modern medicine can provide toward his recovery.

From the economic point of view again the problem of medical care is being worked out on the basis of the voluntary team. Here come the agencies of the type of Blue Cross insurance against the costs of hospitalization, non-profit and private insurance against the costs of sickness, surgery, obstetrics and medical catastrophies. Here through such insurance agencies and through co-operatives and group practice and similar voluntary methods all unite for the good of all and the physician co-operates in order that the quality of the service rendered may be adequate and not conditioned at the low level of economic schemes in which administration rather than scientific knowledge determines the quality of the service rendered.

In every phase of medical care in our nation today there is teamwork. It is a teamwork that has grown out of needs of man but principally out of the advancement of medical science and a recognition of the necessity for co-operation, co-ordination and integration for maximum achievement.

EPITHELIOMAS OF THE LOWER LIP

JOHN B. ERICH, M.D.
Rochester, Minnesota

THE lips are a rather common site for the development of carcinoma. Of all the malignant tumors of the entire body treated at the Mayo Clinic during 1945, 2.3 per cent involved the lips. Carcinoma in this location is definitely a disease of men. At the clinic only a trifle more than 1 per cent of the patients who have this disease are women. More peculiar, however, is the fact that about 98 per cent of these lesions are on the lower lip only.

Malignant tumors which affect the vermilion portion of the lips are for the most part squamous-cell epitheliomas. Practically all such lesions in this location arise primarily in the mucous membrane, although the vermilion border occasionally is invaded secondarily by a squamous-cell or basal-cell epithelioma which starts in the adjacent skin. In size, great variation can be expected in epitheliomas of the lips; this depends on the duration of the growth and its degree of activity. If left untreated, epitheliomas of the lip spread and involve the entire lip. Those on the lower lip may infiltrate the tissues of the cheek or chin, become attached to the periosteum of the underlying bone or actually invade the substance of the mandible itself. These neoplasms may appear to be well circumscribed, elevated and usually ulcerated lesions with indurated margins; some are deeply ulcerated and inflamed, whereas others are large fungating masses. Clinically, little difficulty is encountered in the diagnosis of epitheliomas on the lips, although some of them, particularly the more active types, cannot always be distinguished from inflammatory, tuberculous or syphilitic ulcerations. Because mere visual inspection of growths on the lips does not always lead to a definite diagnosis, at the clinic we are decidedly of the opinion that when an ulcerated lesion does not heal in three or four weeks, a specimen should be removed and examined histologically without further delay. Such a policy leads to the diagnosis and early treatment of many malignant tumors which otherwise would be neglected until they have reached a more advanced stage.

All carcinomas at the clinic are examined microscopically and the degree of malignancy is graded from 1 to 4 (Broders' classification). On study of the grade of malignancy of a large series of cases of primary and untreated epithelioma of the lower lip at the clinic, it was found that in approximately 39 per cent of cases the epitheliomas were of Grade 1 malignancy, in about 52 per cent of Grade 2, in 8.5 per cent of Grade 3, and in 0.5 per cent of Grade 4. Since it is generally accepted that malignant neoplasms of the low grade of malignancy are radioresistant it is extremely important that the grade of activity of all epitheliomas on the lips be determined, particularly when the treatment of the regional lymph nodes is under consideration.

Treatment

The removal of precancerous lesions which are nonmalignant but which are likely to lead to the development of an actual carcinoma will contribute greatly to the control of malignant lesions of the lips. Consequently, my colleagues and I recommend that all lips afflicted with thickened patches of leukoplakia, keratoses, chronic scaling, persistent inflammatory ulcers or recurring fissures receive treatment. Surgical removal of the lesion, rather than irradiation, is the treatment of choice.

The exposed part of the mucous membrane of the lip is completely excised under local anesthesia, and the mucous membrane at the edge of the wound is undermined and sutured anteriorly to the edge of the skin with interrupted fine silk sutures. Because the suture line is located along the mucocutaneous border, scarring becomes almost invisible within a period of two or three months.

The mucous membrane with the lesion removed in this fashion always is examined under the microscope. It is surprising how often evidence of the early malignant change is found, that is, how often the lesion proves to be a Grade 1 squamous-cell epithelioma *in situ*.

Many patients who have frank epitheliomas on the lower lip also may have thickened patches of leukoplakia or keratoses elsewhere on the lip. In these cases, excision of the malignant lesion can

From the Section on Laryngology, Oral and Plastic Surgery, Mayo Clinic, Rochester, Minnesota.
Read at the annual meeting of the American Society of Maxillofacial Surgeons, Minneapolis, Minnesota, October 28, 1947.

be combined with removal of the exposed mucous membrane as just described. Such treatment not only removes the epithelioma but also prevents the development of other epitheliomas on the lip.

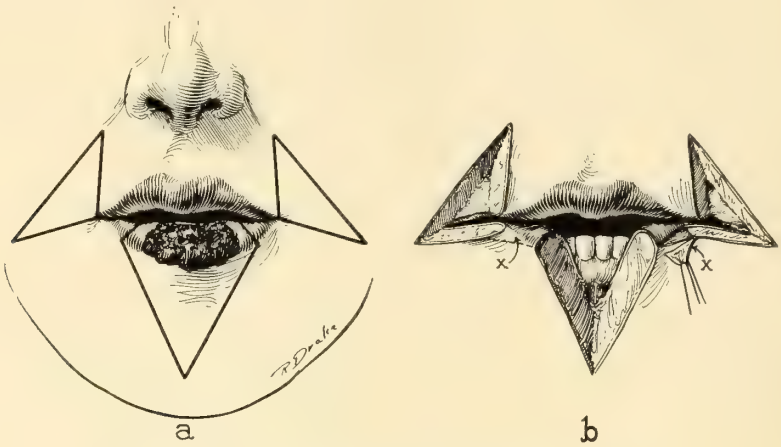

Fig. 1. Large epithelioma of lower lip. Tissue to be removed is outlined in *a*. Lateral incisions into cheeks permit advancement of tissues of cheek to median line to form a new lower lip. However, these lateral incisions also increase width of upper lip, which must be reduced to normal size by removal of triangular portions of skin and subcutaneous tissue at angle of mouth, as in *b*.

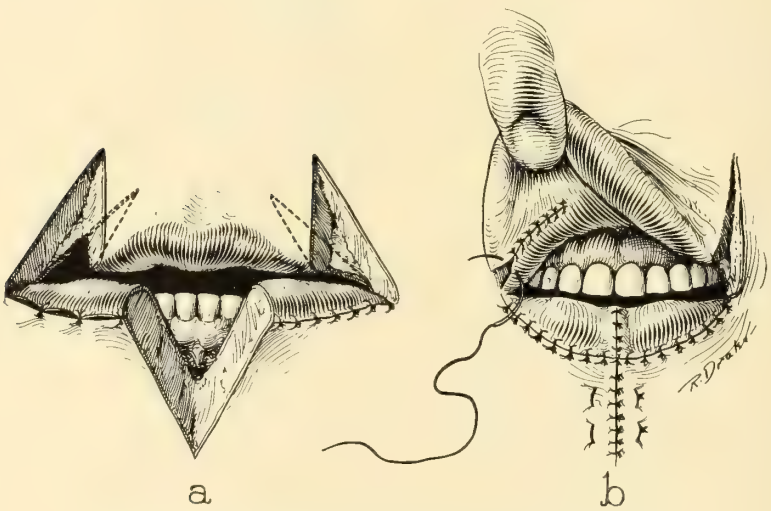

Fig. 2. V-shaped defect, *a*, of lower lip is sutured together in median line *b*. Mucosal and cutaneous edges of lateral incisions are sutured together, *a* and *b*, to form vermilion border for new lower lip. The dotted triangular areas of mucous membrane on either side of upper lip in *a*, when excised and sutured, tend to produce a more normal contour of new angles of the mouth.

In removal of epitheliomas which do not involve more than a third of the lower lip a V-shaped incision is used. After excision of the lesion the margins of the tissue are sutured together. The subcutaneous tissues, muscle and mucous membrane are approximated with catgut sutures and the edges of the skin with interrupted fine silk stitches. When properly executed, this operation leaves an excellent cosmetic result, since the small amount of tissue removed does not change appreciably the width of the oral fissure.

After V-shaped excision of more than a third of the lower lip for large epitheliomas, more extensive plastic correction is required (Figs. 1 and 2). Although the margins of the large V-shaped defect are sutured together as just described, a greatly narrowed oral aperture results,

the width of which must be increased by a plastic operation on the upper lip and cheek at both angles of the mouth. Actually, lateral incisions from the angles of the mouth out into the cheeks permit advancement of the tissues of the cheeks to the median line. This is necessary for establishing the normal width of the lower lip. However, the lateral incisions required in the reconstruction of the lower lip also may increase the width of the upper lip (Fig. 1*b*). This necessitates a reduction of the upper lip to its normal horizontal dimensions by removing a triangular portion of tissue at each angle of the mouth. The end result of this plastic procedure is most satisfactory, both from a cosmetic and a functional standpoint, even in cases in which practically the entire lower lip has been removed. Some surgeons prefer not to reject the triangular pieces of cheek tissue at each angle of the mouth, but to cut them as pedicle flaps and to turn them down for reconstruction of the lower lip; however, my colleagues and I believe that better results are obtained when these triangular pieces of tissue are discarded.

When a large epithelioma is confined to one side of the lip, a satisfactory reconstruction of the lip can be accomplished often by a plastic operation at only one angle of the mouth, that on the same side as the lesion.

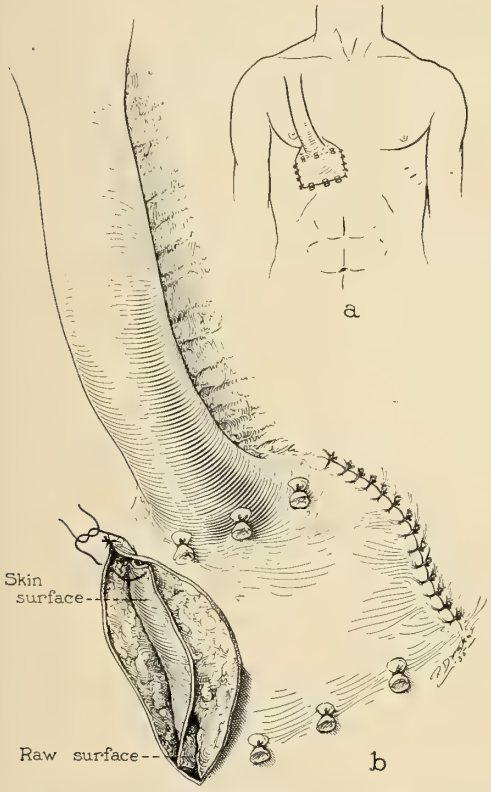

Fig. 3. Method of reconstructing the entire lower lip by means of a tube flap from the chest; position of tube on anterior portion of thorax, and lower end of flap, which is lined with a full-thickness skin graft, are shown.

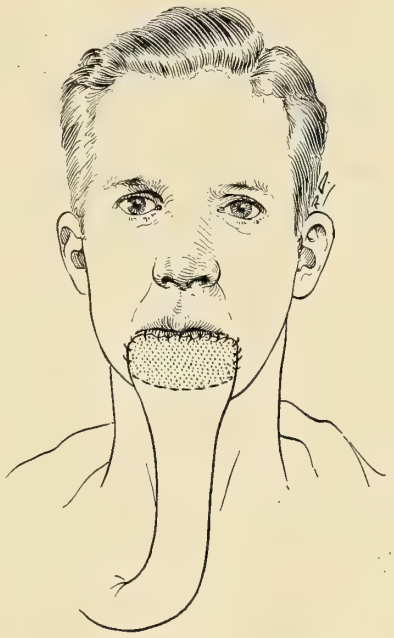

Fig. 4. The lower end of the tube flap on chest is elevated and sutured in position to form the new lower lip. The shaded portion indicates the lining formed by the full-thickness skin graft.

Whenever an epithelioma of the lower lip invades the tissues of the cheek, its removal cannot be followed immediately by plastic closure. Furthermore, if a large epithelioma of the lower lip has become attached to the periosteum of the mandible or has actually invaded the bone, it should be removed by surgical diathermy (electrocoagulation). The entire growth is excised by the cutting cautery, while the underlying periosteum and bone to which the growth is attached are thoroughly electrocoagulated. This form of treatment results in a sequestrum of bone which gradually separates and which can be removed in two or three months. A radical procedure of this type, we believe, is necessary to cure the malignant lesion, but it unavoidably produces a conspicuous facial defect. Reconstruction of the lower lip and chin can be carried out eventually after it is fairly certain that malignant growth will not recur. This means a delay of twelve months after operation.

For complete loss of the lower lip, plastic reconstruction is necessary. Sufficient tissue can be procured advantageously through the use of a tube flap from the chest, which will supply an abundance of skin for the restoration (Figs. 3 and 4). When a tube from the chest is used for such a purpose, the flap must be made relatively long from end to end and large in diameter. Consequently, much time is required for the establishment of proper blood supply in such a tube. After the primary operation in which the flap is elevated from the chest and tubed, it is best to wait about three months before its lower extremity is raised. Either end of such a tube flap may be employed to form the new lower lip. Since the color of the skin in the clavicular or infraclavicular regions resembles more closely that of the face than does the skin over the lower part of the chest or abdomen, the upper end of the tube flap from the chest is best from the cosmetic point of view. However, its use incurs one disadvantage, namely, that of extending the time necessary to complete the plastic procedure, because the lower termination of the tube first must be transferred to the neck before the upper part can be elevated to the face.

The portion which is to form the lip must be lined with skin. This can be accomplished by folding the end of the tube, or better, by the use of a full-thickness skin graft (Fig. 3). A vermilion border to the lip may be constructed by sliding flaps of mucous membrane from the cheeks across the upper free margin of the graft.

At the clinic, the use of radon seeds, radium plaques or external irradiation for the local primary lesion is confined generally to large epitheliomas of Grade 4 of the lips, to carcinomas of elderly individuals or to malignant lesions on the lips of patients for whom the surgical risks are extremely great.

Since metastasis to the regional lymph nodes is likely to occur, the therapeutic management of patients who have carcinoma of the lips should include not only removal of the primary lesion but treatment of the nodes in the neck as well. My colleagues and I believe that the most effective method of preventing cervical metastasis is to block off the lymph channels by surgical removal of the cervical nodes. Because the submental and submaxillary nodes are most likely to become involved, we recommend that every dissection of cervical nodes include first dissection of submental and submaxillary nodes and also the nodes near the upper part of the jugular vein. If, on microscopic examination by the frozen section method, one or more of these nodes is found to be involved by a metastatic lesion, an immediate block dissection of the deep cervical lymph nodes is carried out on the involved side. I would like to repeat that at the clinic bilateral dissection of the submental and submaxillary nodes and the nodes along the upper part of the jugular vein is carried out as routine procedure whenever any cervical nodes are removed. A block dissection of the deep nodes is resorted to only when one or more nodes in the submental, submaxillary or upper part of the jugular regions are found to be involved. When block dissection of the deep nodes is undertaken, removal of the sternocleidomastoid muscle is advocated only when lesions of a high grade of malignancy or extensive cervical involvement by the malignant process is present.

Dissection of the cervical nodes for carcinoma of the lips then is carried out as a prophylactic measure to prevent metastasis as well as a curative form of therapy to remove cervical nodes already involved by the malignant process. Just which patients should be treated by dissection of the cervical nodes is determined by many factors. At the clinic the decision rests largely on the grade of malignancy of the primary lesion. We have found that squamous-cell epithelioma of Grade 1 practically never produces metastasis to the cervical nodes unless the lesions are badly infected or inflamed. Consequently, patients who have epithelioma, Grade 1, without any evidence of cervical extension are not subjected to dissection of the cervical nodes. However, as previously stated, an inflammatory reaction due to infection or caustic agents can augment the activity of an epithelioma; if a primary lesion of Grade 1 on the lip is badly inflamed, it then may be justifiable to consider removal of the regional lymphatics.

Squamous-cell epitheliomas of Grade 2 or 3, on the lips, are so likely to produce cervical metastasis that dissection of these nodes in the neck is a routine procedure at the clinic in all such cases. Irrespective of the size of a primary lesion of Grade 2 or 3, dissection of the cervical nodes is to be recommended, and the most satis-

A SURVEY OF CESAREAN SECTION IN MINNEAPOLIS, MINNESOTA, IN 1946

CLAUDE J. EHRENBERG, M.D.

Minneapolis, Minnesota

CESAREAN section, according to recent surveys in this country, has shown some increase in incidence. More noteworthy, however, is the marked decrease in maternal and fetal mortality. In order to compare the results in this community with those in other localities, a survey of the cesarean sections performed in Minneapolis in the year of 1946 was undertaken. For comparison, only one survey made in the immediate vicinity could be found. This was a five-year study of cesarean sections in Ramsey County, Saint Paul, Minnesota, by Skinner, in which observations were made of the years from 1937 through 1942. During this period, 28,868 hospital deliveries were recorded with 434 cesarean sections, an incidence of 1.5 per cent, which varied from an incidence of 0.5 to 2.8 per cent in the different hospitals in Ramsey County. There were eight maternal mortalities, an incidence of 1.84 per cent, and the fetal mortality of 11.2 per cent.

Minneapolis has a population of approximately 500,000. During the year 1946, 15,582 live births were recorded by the City Board of Health, a rate of 30.8 per 1,000 population; 436 infant deaths and thirteen maternal deaths were recorded, resulting in rates of 27.8 and .8 per 1,000 population, respectively (Table I).

TABLE I. MINNEAPOLIS HEALTH DEPARTMENT RECORDS, 1946

Total recorded live births	15,682
Rate per 1,000 population	30.8
Total recorded infant deaths	436
Rate per 1,000 live births	27.8
Total recorded maternal deaths	13
Rate per 1,000 live births	0.8

Of the thirteen maternal mortalities, four resulted from abortions and one from early ectopic pregnancy, leaving eight obstetrical maternal deaths.

Three hundred and three stillbirths were recorded, making the total recorded births in the city 15,985. The total number of deliveries reported by the hospitals of Minneapolis in the same year was 15,556. The number of multiple births and the precise number of stillbirths occurring in the hospitals was not examined, but, assuming the usual incidence of multiple births, the incidence of hospital deliveries is probably about 99+ per cent.

Minneapois has ten voluntary hospitals in which the obstetrical departments are utilized exclusively for private patients; the Minneapolis General Hospital, where obstetrics is solely a service for the indigent of the city; the University Hospitals in which the obstetrical facilities are employed largely for the obstetrical abnormalities of the semi-indigent and indigent of the state; and the Maternity Hospital, an exclusively obstetrical hospital, in which the service is approximately 60 per cent private patients, 30 per cent Community Health (partial pay) patients, and 10 per cent unmarried mothers.

Of the 15,556 recorded deliveries in the hospitals of Minneapolis in 1946, 405 were by the cesarean section method, an incidence of one in thirty-eight (2.6 per cent). Only two maternal mortalities occurred. The first, attributable to an amniotic fluid embolus, occurred during an operation for complete placenta previa, and the second, in connection with a case of fulminating preeclampsia. In addition, one postmortem cesarean section was performed on a patient whose death occurred from the bulbar type of anterior poliomyelitis a few minutes before. A living baby was delivered, but death occurred shortly after.

TABLE II.

Infant deaths per 1,000 live births (Board of Health)	27.8
Infant deaths (cesarean section)	16.
Infant deaths (cesarean section)	3.9%
Infant deaths (cesarean section) per 1,000 live births	41.1
Infant deaths (causes)	
Abruptio placenta	7.
Erythroblastosis	2.
Prematurity	4.
No reason given	3.
Total	16.

Infant deaths recorded with cesarean section during this period amounted to sixteen, an incidence of 3.9 per cent, or 41.1 per 1,000 live births as compared to an over-all infant death record in the city of 27.8 per 1,000 live births (Table II). An analysis of infant deaths revealed that

Presented at the Semi-annual meeting of the Minnesota Obstetrical and Gynecological Society, Saint Paul, Minnesota, November 7, 1947.

TABLE III. CESAREAN SECTION DURING THE YEARS 1937-1945

Author	Locality	Years	No. C. S.	%	Deaths	%
Keetel	Wisconsin	1937	1021	1.9	35	3.4
		1938	1233	2.2	19	1.5
		1939	1221	2.2	27	2.2
		1940	1439	2.5	32	2.2
Williams	Philadelphia	1937	811	2.7	20	2.5
		1938	795	2.6	13	1.6
		1939	857	2.8	11	1.3
DeNormandie	Mass.	1937	2082	3.2	66	3.1
		1938	2216	3.4	60	2.7
		1939	1984	3.1	54	2.7
		1940	2312	3.4	41	1.7
		1941	2436	3.3	52	2.7

Bell	Oakland	1943	290	4.0	2	.68
Mack						

seven occurred in connection with abruptio placenta, two were due to erythroblastosis, seven were assumed to be due to prematurity as the babies were delivered prior to the thirty-second week, and in three cases no reason was given.

If the record of cesarean sections in Minneapolis is compared to those reported from other communities in the country in recent years, the trends would seem to be parallel, namely, a slight increase in the incidence of the procedure with a reduction of maternal and fetal mortality (Table III). Further, a comparison to the Ramsey County survey shows the same general improvement in this locality as noted in other communities.

The incidence of cesarean section in the individual hospitals of Minneapolis is presented in Table IV.

Neither the number of deliveries in any hospital nor the status of the attending staff as to general practice or limited obstetrical practice seems to influence the percentage incidence. For instance, hospitals B and G are attended almost exclusively by general practitioners, while hospitals D, F and K are attended almost entirely by obstetric specialists. The high incidence of cesarean in hospital M is to be expected because of the selectivity of the patients.

Of the 405 cesarean sections performed, 240 were of the classical type, while 156 were low cervical in character. Seven cesarean hysterectomies were performed, an incidence of 1.7 per cent. This is considerably lower than reported by Reis and DeCosta in their own series and in most of the other series tabulated by them. However, it compares favorably with DeNormandie's studies of cesarean section in the State of Massachusetts, in which the incidence of the Porro section was 1.3 per cent. Two things are noteworthy in connection with the seven cesarean hysterectomies. First, five were performed in one hospital; and second, in no case was the operation performed because of potential infection. In two cases myomas were present. In three cases the indication was given as previous cesarean section, one complicated by diabetes. One patient was a gravida 9, para 8 woman with a partial placenta previa, and in one case the indication was designated as hyperemesis gravidarium in a gravida 2, para 0 woman, aged thirty-four. In this series, there was only one vaginal cesarean section and one abdominal pregnancy. The morbidity relationship to type of operation is shown in Table V.

TABLE IV

Delivery	Hospitals	C.S	Per cent
2692	A	85	3.2
2627	B	77	2.8
1929	C	64	3.3
1460	D	54	3.7
1413	E	19	1.3
1161	F	7	.6
1028	G	10	1.
809	H	21	2.6
802	I	16	2.
644	J	21	3.2
365	K	4	1.
325	L	5	1.5
301	M	22	7.

TABLE V

Type of Operation	No. Cases	Morbid	Nonmorbid %
Classical	240	67 (28)	173 (72.)
Low Cervical	156	33 (21)	123 (79.)
Cesarean hysterectomy	7	2 (28.5)	5 (71.5)
Vaginal	1		1 (100.)
Abdominal pregnancy	1		1 (100.)

An examination of the qualifications of the individuals performing the operations in this series reveals that of the 405 cases, 250 were executed by qualified obstetricians either individually or in consultation, as compared to 155 done by general practitioners or surgeons. All of the Porro sections, the vaginal cesarean section and the abdominal pregnancy section, were attended by obstetricians. Of the 240 classical cesarean sections, 126 were performed by the general practice group while 114 were executed by the qualified obstetrical group, a ratio of approximately 1 to 1. In contrast, of the 156 low cervical operations, twenty-seven were done by the former and 129 by the latter groups, respectively, a ratio of 1 to 5. The above may indicate reluctance on the part of the general practitioner to undertake the low cervical operation, but it does not account for the

high proportion of classical cesarean sections performed by the qualified obstetricians, in spite of the generally recognized virtues of the low cervical operation.

Poor records permitted only 296 of the 395 cases of classical and low cervical cesarean sections to be studied for morbidity in relationship to the status of length of labor and the condition of the bag of waters. Although the number of cases is too small to draw definite statistical conclusions, the exhibition of the trends may be suggestive, as shown in Tables VI and VII.

TABLE VI

In Labor	No. Cases	Morbid	Non-morbid
Membranes ruptured			
Classical	19	10 (53%)	9 (37%)
Low cervical	11	5 (45%)	6 (55%)
Membranes not ruptured			
Classical	25	11 (44%)	14 (56%)
Low cervical	14	1 (7%)	13 (93%)

TABLE VII

Not in Labor	No. Cases	Morbid	Non-morbid
Membranes ruptured			
Classical	10	5 (50%)	5 (50%)
Low cervical	9	3 (33%)	6 (66%)
Membranes not ruptured			
Classical	118	20 (17%)	88 (83%)
Low cervical	79%	11 (14%)	68 (86%)

Thus, in these comparisons the low cervical operation may seem to have an advantage in all conditions except when the patient is not in labor and has intact membranes.

The indications for cesarean section in this series is revealed in Tables VIII, IX, and X.

TABLE VIII

Multiple	155
Single	250
Obs.	383
Med.	22

TABLE IX

	Per Cent
Disproportion	26
Previous cesarean section	20
Toxemia	12.7
Non-convulsive	(6.3)
Convulsive	(6.4)
Placenta previa or abruptio	11
Abnormal presentation	7
Medical reason (heart, t.b., diabetes, vascular disease)	6
Sterilization	4.8
Elderly primipara	3
Previous plastic	1.6
Erythroblastosis	1.1
Others	10.8

TABLE X. INDICATIONS, LISTED AS OTHERS

Obstructing tumor	Contraction ring
Carcinoma of the cervix	Fetal distress
Ruptured uterus	Prolapsed cord
Anomaly of genital tract	Fetal malformation
Uterine myoma	
Uterine inertia	Prolonged labor

Inspection of, and comment on, the indications is not noteworthy, as it parallels generally those of other reported series.

The choice of anesthesia is disclosed in Table XI.

TABLE XI. ANESTHESIA

Cyclopropane and/or Nitrous Oxide and/or Ethylene and/or Ether	202
Local infiltration and/or Pentothal Sodium and/or inhalation	150
Spinal and/or inhalation and/or local infiltration	41
Others (Ether, Ethylene)	7
Not reported	4

Cyclopropane with other inhalants would appear to be the prevailing choice, with local infiltration plus additions next. Morbidity in relation to the type of anesthesia is shown in Table XII.

TABLE XII. ANESTHESIA MORBIDITY

	Morbid	Non-morbid
Cyclopropane group	55 (22%)	147 (78%)
Local infiltration group	31 (20%)	119 (80%)
Spinal group	11 (27%)	30 (73%)

There was no evidence of advantage from the standpoint of morbidity in the type of anesthesia used.

The number of sterilizations occurring in this series of cesarean sections would seem, at first glance, to be startling. However, Lull, reporting on cesarean sections in Philadelphia for the years 1931 and 1941, reveals an incidence of 15 and 22 per cent, respectively. The incidence of sterilization in connection with or following cesarean section in this series is revealed in Table XIII.

TABLE XIII

Hospital	C.S.	Sterilizations	Per Cent
A	85	19	22.
B	77	1	1.3
C	64	11	17.
D	54	10	18.5
E	19	3	15.6
F	7	1	14.
G	10	0	
H	21	7	33.3
I	16	6	37.5
J	21	5	20.
K	4	0	
L	5	2	40.
M	22	8	35.

A closer study of the records in relation to hospital incidence suggests that the indication for sterilization is a patient-physician relationship, because, with a few exceptions, the sterilizations were done in private hospitals.

(Continued on Page 995)

ACUTE CORONARY INSUFFICIENCY

HERMAN J. WOLFF, M.D., PH.D.
Clinical Assistant Professor of Medicine, University of Minnesota
Saint Paul, Minnesota

A BROADENING medical comprehension of coronary artery disease has rendered necessary some revision in our conceptions of the physiological abnormalities in this group of diseases and their clinical, electrocardiographic, and laboratory manifestations.

The changing concept probably owes much of its impetus to the work of the German cardiologists, which is aptly summarized by Büchner[2] in a volume entitled *Die Koronärinsuffizienz*, published in 1939. It is interesting to note by way of comparison that a standard and excellent American text on heart disease published as recently as 1945 mentions coronary insufficiency only in a passing manner. Examination of two recent textbooks of pathology (one published in 1944 and one in 1945) reveals only a brief mention of coronary insufficiency in one. Perhaps since the spectacular clinical identification of coronary thrombosis, dating back to Herrick[3] in 1912, correlating the clinical and postmortem pathological changes has so occupied the attention of clinicians that they have failed to realize until more recently the multitudinous changes in physiological function, which can lead to symptoms of coronary insufficiency.

Initiated by the German school and fostered in this country by such men as Levy,[4,5] Master et al,[6-13] Boas,[1] Barnes and his collaborators,[14] a newer classification of coronary disease which embraces the various forms of acute coronary insufficiency has been developed.

Acute insufficiency of the coronary arteries implies a physiological or pathological inability of these arteries to supply the myocardium in whatever state of activity it may happen to be. Perhaps this may be simply stated as that which is necessary for the satisfaction of the myocardium in homeostasis.

A brief résumé of the conditions which may bring about acute coronary insufficiency must include physiologic effort, emotional strain, excessive use of tobacco, paroxysmal tachycardia, auricular fibrillation or flutter, heart failure, shock (surgical or nonsurgical), hemorrhage, high altitude flight, severe anemia, aortic insufficiency and stenosis, syphilitic coronary arteritis, digestive shift in blood flow, insulin shock, excess adrenali, gastroenteritis with pooling of the blood in the abdominal cavity, sexual intercourse, straining at stool, extremes of temperature, hyper- and hypothyroidism, pulmonary infarction and embolism, as well as reflex effects from other viscera.

The clinical pictures, as well as laboratory findings, presented in the four main types of acute coronary insufficiency are summarized in Tables I and II. The four groups are as follows:

Group I.—Acute evanescent coronary insufficiency or angina pectoris. The term angina pectoris should be retained because the clinical picture of pain and its radiation, as well as its relation to effort, exertion, emotion, and exposure to cold, and its relief by nitroglycerine, sets apart this type of insufficiency. The physiologic mechanism is undoubtedly a disproportion between the coronary blood flow and the needs of the heart muscle.

Group II.—Acute temporary coronary insufficiency of such severity and duration as to fail to produce demonstrable changes in the myocardium but of greater duration and severity than that seen in angina pectoris.

Group III.—Acute temporary coronary insufficiency of such severity and duration as to produce clinically demonstrable myocardial changes, chiefly subendocardial necrosis, but often referred to as myocardial infarction without thrombosis.

Group IV.—Acute permanent coronary insufficiency with massive myocardial infarction (coronary thrombosis). It might be mentioned that while acute coronary insufficiency may be productive of myocardial infarction, conversely, true coronary thrombosis, in the presence of an exceptional collateral circulation, may actually fail to produce myocardial infarction.

While at first glance it may seem that the difference between Groups I, II, and III is chiefly one of duration, there are in reality many other differential features worthy of mention. As a

*Presented before the Minnesota Society of Internal Medicine, May 31, 1947.

premise it may be stated that coronary sclerosis is at least a predisposing factor in all four groups (save perhaps occasionally in leutic aortitis or in cases of severe anemia or hemorrhage).

solute delineation may be offered, it is suggested that more protracted pain is more apt to be followed by definite change in the myocardium (Group III cases). Various other clinical fea-

TABLE I. ACUTE CORONARY INSUFFICIENCY

	Grade I Acute Evanescent Angina Pectoris	Grade II Acute Temporary Without Necrosis	Grade III Acute Temporary With Necrosis	Grade IV Coronary Thrombosis
Coronary Sclerosis	Usually Present +	Usually Present + or ++	Present + to +++	Present + to ++++
Exciting Cause	Emotion, Excitement, Exertion, Food, etc.	Same as for Grade I	Same as for Grade I	May be absent often at rest
Pain	Transient	Variable—Severe—often fairly prolonged	Variable, more prolonged than in II	Prolonged usually
Nitroglycerine	Relief	Variable, may relieve	Probably little relief	No relief
Nausea and vomiting	Absent	Rare	Rare	Frequent
Shock	Absent	Rare	Rare	Common
Heart sounds	Normal	Usually normal	May be normal, gallop rare	Gallop frequent, friction rub frequent
Heart rate	No change	No change usually	Tachycardia slight or absent	Tachycardia common, Arrhythmia common
Failure	Absent	Rare	Rare	Common

TABLE II. ACUTE CORONARY INSUFFICIENCY

	Grade I Acute Evanescent Angina Pectoris	Grade II Acute Temporary Without Necrosis	Grade III Acute Temporary With Necrosis	Grade IV Coronary Thrombosis
Fever	None	None	Slight	Usual (101°-103°)
Leucocytosis	None	None	Slight, variable	Nearly always—moderate to high grade
Erythrocyte Sedimentation rate	Normal	Normal	Slight Elevation	Elevated
Urobilinogen	None	None	None	Occasionally present
E. C. G.	No change— No ECG evidence— May occasionally show:— "RST" depression "T" inversion Absent "Q" waves	"RST" Depression "T" inversion Absent "Q" waves Prompt return to previous pattern	"RST" Depression "T" inversion Absent "Q" waves Usually prompt return to previous pattern	"RST" Elevation Cove-plane "T" progressing to "T" inversion. "Q" waves usually present Slow progressive pattern
Duration	Momentary	Hours to days	Days to weeks	Weeks to months
Myocardial pathology	None	None	Sub Endocardial Necrosis Also involving Base of Papillary Muscles	Massive Necrosis involving Endocardium Myocardium Pericardium
Compensable	No	Yes (?) (Master)	Yes (?) (Master)	No (?)

The exciting cause in the first three groups is definitely at variance with that to be found in Group IV, and this is especially important with regard to possible compensability of the various types of coronary insufficiency. The duration of pain is also of some significance, particularly in differentiating Groups II and III. While no abtures as seen in the table are relatively self-explanatory. With reference to physical and laboratory findings as shown in Table II, the presence of fever in acute insufficiency would definitely suggest a Grade III type of change; and more especially, elevation of the leukocyte count and sedimentation rate in the Group III cases

serves to differentiate them from the Group II cases.

The further differentiation of Group III cases from Group IV cases is accomplished by the electrocardiogram. The changes so characteristic of coronary thrombosis are not found in any of the insufficiency groups of lesser grade; and this is, of course, compatible with the pathologic changes which are characteristic of coronary thrombosis, namely, a through and through necrosis of the myocardium with involvement of endocardium, myocardium, and pericardium. In contradistinction, Group III cases will show a subendocardial necrosis due to failure of oxygenation at the terminal ends of the subendocardial vessels. These same changes are found in the bases of the papillary muscles. Similar changes are not seen in Groups I and II.

With reference to compensation, which was mentioned earlier, it is interesting to note that Master considers the acute insufficiencies, not due to thrombosis, as compensable. In the classification which is here presented, this would include cases in Groups II and III, which are apt to come on as a result of strenuous physical exertion; and while the subject certainly can be debated almost *ad infinitum*, there seems to be a moiety of truth in the fact that many coronary thromboses occur during inactivity, whereas most of the other insufficiency syndromes have a definite precipitating factor which may be associated with compensable activities.

With this classification in mind, a survey of two illustrative cases would seem to be in order.

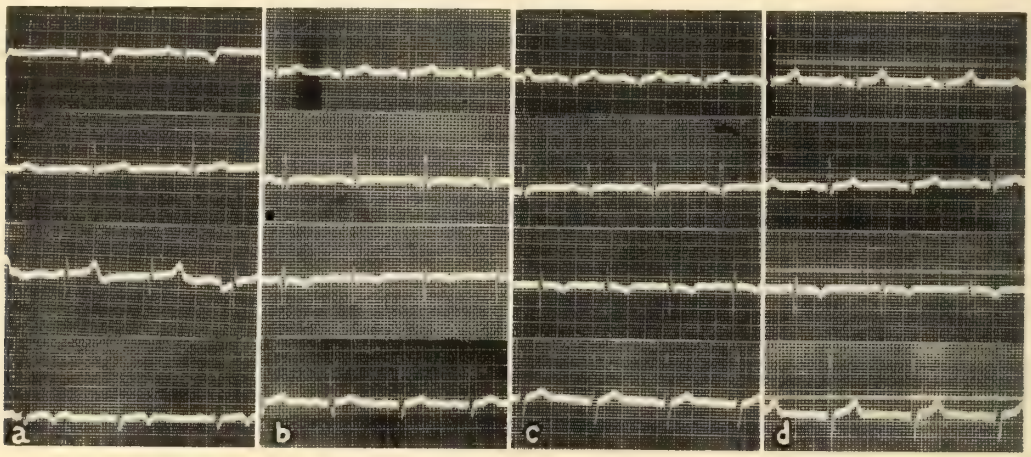

Fig. 1.

Case Reports

Case 1.—The patient, whose essential data are summarized in Table III, was a thirty-seven-year-old, white, married man, who presented himself at the Charles T. Miller Hospital in Saint Paul on September 30, 1944, with a history of acute, severe, and moderately prolonged retrosternal pain, which had been present for three hours at the time of admission. Radiation into both shoulders and arms had occurred since early morning. The electrocardiograms which follow sequentially in Figure 1 are those which have been indicated

with an asterisk on Table III. It will be noted that the initial electrocardiogram (Fig. 1a) shows a rather bizarre picture consisting of a sharp inversion of T1 with a slight depression of ST1 and definite inversion of T4, which has a slightly positive component as well. tunately, prior tracings are not available, so that the eventual establishment of the Q3 T3 pattern must be considered to be either a residual of a previous thrombosis or as evidence of recent thrombosis. The way in which these changes appear, however, suggests more

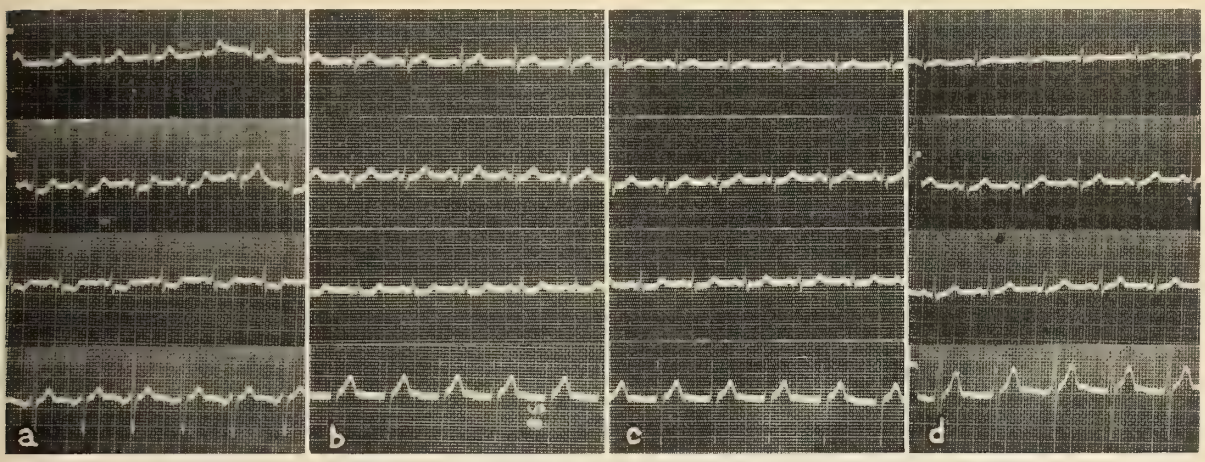

Fig. 2.

TABLE IV

R.G.M. (I)	E.C.G.	Pulse	Temperature	Blood Pressure	White Blood Count	Erythrocyte Sediment Rate (West) m.m.	Pain	Dyspnea
1-31-45	I*	104	97.0	148/102	9,850	9	Severe	Slight
2- 1-45	II*	100	97.4	170–158/100–94	9,100	5	0	0
2- 2-45		100	99.0	142–132/98–84	11,050		0	0
2- 3-45	III*	84	99.0	148–144/92–90	10,300	9	0	0
2- 5-45	IV	80	98.2	140–130/98–80	6,100	12	0	0
2- 7-45	V	74	99.0	124–122/76	7,950	8	0	0
2-23-45	VI*	78	98.4	142/84	9,350	3	0	0
4-25-45	VII	80	98.2	146/84		3	0	0

These findings are characteristic of acute insufficiency and well satisfy the Levy requirements for a diagnosis of coronary insufficiency. These spontaneous changes are in marked contrast to those seen in the next electrocardiogram (Fig. 1b), made forty hours later, wherein a complete reversal to a positive T1 and T4 has taken place; and we are now confronted with a Q3 T3 pattern. These same changes are present in the following two electrocardiograms (Fig. 1, c and d) which were taken twelve and twenty-four days after the initial tracing. It is interesting to recollect that there was a very slow change in the sedimentation rate, with no definite elevation occurring for five days, and a rather more marked elevation occurring at the end of two weeks. The interpretation of these tracings may be made along either one of two definite and probably acceptable variants. However, there can be little doubt that the original tracing must be considered as an excellent example of acute coronary insufficiency. Unfor- strongly the presence of a previous disturbance which makes the Q3 T3 pattern possible. One is forced to infer that the acute insufficiency present at the time of admission, together with the rather definite changes in the sedimentation rate, make this an instance of Group III coronary insufficiency, namely acute coronary insufficiency associated with definite subendocardial necrosis. This patient remained in the hospital four weeks, and was clinically well with the exception of a psychosomatic residive upon his discharge.

Case 2.—This case is of interest because in this patient two episodes, the first typical of Group II and the second typical of Group IV, occurred at an interval of approximately twenty months. The significant data for the Group II episode, or acute coronary insufficiency without necrosis, are shown in Table IV. The patient is a forty-one-year-old, white, married man, who pre-

sented himself at the office on January 31, 1945, with a history of retrosternal pain radiating over his entire chest into the left shoulder, and which lasted one hour. It occurred originally at 9:00 o'clock in the morning, and returned at 2:00 o'clock in the afternoon and re-

Table V were obtained. At this time pain in the chest was not an outstanding feature. The attack was ushered in by syncope, and the original tracing (Fig. 3a) made in the office showed changes very suggestive of a posterior infarction due to coronary thrombosis. Although

9-23-46	XI*	74	98.8	128/84	10,150	37	0	slight
9-26-46		66	98.2	130/84	7,000	20	0	slight
9-30-46	XII	66	98.4	136/84			0	0
10- 1-46		72	98.2	142/86	5,490	9	0	0
10- 4-46	XIII	70	98.0	142/84	8,650	6	0	0

mained for slightly longer than one hour. He noticed perspiration and some shortness of breath at the time. Those electrocardiograms marked with an asterisk in Table IV are illustrated in Figure 2. It will be noticed that at no time was there a marked leukocytosis and that the sedimentation rate remained normal throughout the entire course. The initial electrocardiogram (Fig. 2a) shows a well defined depression of ST2 and ST3 which changes satisfy the Levy postulates for acute coronary insufficiency. The prompt return to normal as shown in the second electrocardiogram (Fig. 2b) is striking; and the maintenance of a normal state as shown in the following two tracings (Fig. 2, c and d) is equally striking. This patient felt entirely well twenty-four hours after the episode and remained so for the ensuing twenty months, when the data shown in the leukocyte count failed to demonstrate much change, the sedimentation rate certainly was significant. The following electrocardiograms (Fig. 3, b and c) show the progress of this very evident myocardial infarction. This case is most interesting and instructive in that it demonstrates marked evidence of coronary insufficiency without necrosis occurring along the distribution of the posterior coronary artery; and twenty months later a second attack was attended by findings of a definite thrombosis or complete occlusion in the distribution of this same vessel.

In summary, it would seem advisable to bear in mind that acute coronary insufficiency is a condition which is limited neither to the acute

evanescent changes of angina pectoris on the one hand, nor to the cataclysmic changes of coronary thrombosis on the other. From the multitude of clinical situations between these extremes, it has seemed possible to formulate two categories. In these subdivisions, the one without and the other with necrosis, there are two clinical syndromes founded upon the same premise, the Group III cases being productive of subendocardial necrosis and sedimentation rate changes, together with a longer clinical course and somewhat more severe symptomatology than that seen in the Group II cases. It would seem entirely possible, and probably advisable, to classify any symptomatic disturbance of the coronary physiology into one of these four groups, and by so doing, to express in definite terms a clinical picture or syndrome immediately understandable to all clinicians.

A SURVEY OF CESAREAN SECTION IN MINNEAPOLIS

(Continued from Page 989)

Discussion

Recently Mack stated, "With the cognitant increased incidence of cesarean section on the one hand and the lowered mortality on the other, one might well ask whether too many sections are now being performed or whether too few took place in former years." A comparison of the results of cesarean section in Minneapolis in 1946 to the results in Ramsey County from 1937 through 1942, may to some extent answer both of these questions in the affirmative. The high fetal mortality in the Ramsey County series could be interpreted as an unnecessary delay for the operation. On the other hand, study of the maternal deaths individually in this same series might deny this conclusion. Rather, it would suggest an improvement in surgical techniques, methods of anesthesia, and the more recent advantages of the sulfonamides and especially the antibiotics.

Summary

1. A survey of cesarean sections in Minneapolis for the year 1946 is presented and compared to an earlier one in an adjacent area.

2. Roughly the results parallel those of surveys made in other localities in this country, in that the incidence is somewhat increased but the maternal mortality is significantly lower.

3. There is a lower morbidity from the low cervical type of operation, but the choice of anesthesia seems of no importance in this connection.

4. Cesarean section in Minneapolis, as revealed in a study of the cases in 1946, shows a higher maternal and infant mortality when compared to normal delivery for the same period. However, it must be concluded that cesarean section is done for relatively definite indications that jeopardize the life of the mother or the baby, a situation that cannot be analyzed statistically when related to normal vaginal delivery.

PRIMARY IDIOPATHIC SEGMENTAL INFARCTION OF THE GREATER OMENTUM

CHARLES S. JOSS, M.D., and JOSEPH HYDE PRATT, M.D.
Rochester, Minnesota

THE infrequent occurrence of primary idiopathic segmental infarction of the greater omentum was revealed when, in a review of the available literature,[6, 9] only twelve authentic instances of the condition could be found.[3] The present report is intended to bring attention to this apparently rare pathologic condition, which is of surgical significance because its symptomatologic features are similar to those of other acute intra-abdominal lesions. We wish, also, to report such a case in which the lesion was seen at the Mayo Clinic recently.

Antecedent Studies (Table I)

Johnson, in 1932, apparently was the first to record primary segmental infarction of the greater omentum. In his case the patient was a man, sixty-three years old, for whom the diagnosis of acute suppurative appendicitis with localized peritonitis had been made. At surgical exploration a portion of the greater omentum was found to be much thickened, infiltrated and partially gangrenous because of thrombosis in the omental vessels. An uneventful convalescence and recovery followed resection of the gangrenous part of the omentum. This case was complicated by the fact that the tip of the omentum was adherent to the scar resulting from repair of an old hernia, but the vessels were not twisted in their course at any point. Johnson said he thought that the etiologic factors leading to thrombosis of these vessels may include slowing of the blood stream in the omentum, first by the fixation of the organ to the old abdominal scar and, second, by the arteriosclerotic condition of the walls of the vessels, as was found at pathologic examination. Aortic regurgitation had also been noted at the physical examination.

Hines, in 1934, reported a case in which hemorrhagic infarction of the greater omentum involved the major portion of the omentum, but in this case the infarction was secondary to thrombosis of the portal vein. For this reason, Hines' case has not been included in the present review of this subject. Berger has reported a case of thrombosis of the left gastro-epiploic vein which resulted in a hemorrhagic infarction of the left third portion of the greater omentum. In this case the thrombosis in question was not associated with other venous thromboses in the abdomen, but the patient had cardiac insufficiency secondary to arteriosclerotic, hypertensive, syphilitic heart disease of several years' duration, which may have been a contributory factor to the thrombosis. Validity of the inclusion of this case in this series is debatable.

Pines and Rabinovitch have reported a series of six cases of apparently true primary idiopathic segmental infarction of the greater omentum which were collected from the files of the Jewish Hospital, Brooklyn, New York, from 1915 to 1939. This is the largest single series of such cases recorded in the literature. All patients in this series preoperatively had received the diagnosis of acute appendicitis, and all recovered after surgical exploration and resection of the infarcted portion of omentum. These authors pointed out that the symptoms of omental infarcts, in general, mimic those of acute appendicitis, with pain in the right lower quadrant of the abdomen being a more or less constant feature. The disproportion between abdominal tenderness, duration of symptoms and abdominal rigidity was pointed out as another striking feature of the syndrome of this disease. The abdomen usually is widely and definitely tender to deep palpation, but abdominal rigidity is not nearly so marked as might be expected when the possible duration of the complaint and the definite tenderness are considered. The authors also commented on marked hyperesthesia of the skin as an outstanding symptom which is not commonly seen in other acute intra-abdominal lesions. They felt that the mechanism involved in the formation of omental thrombi is similar to that produced experimentally on stretching a vein, with subsequent thrombosis caused by the injury of the endothelial lining of the vein; thus, the condition is secondary to some form of trauma.

Bang-Dietrichson recorded a case in which a woman, forty-six years old, with apparent pri-

Dr. Joss is a Fellow in Surgery, Mayo Foundation, and Dr. Pratt is in the Division of Surgery, Mayo Clinic, Rochester, Minnesota.

TABLE I. PRIMARY IDIOPATHIC SEGMENTAL INFARCTION OF THE GREATER OMENTUM: CASES REPORTED IN LITERATURE

Reported by	Patient		Leukocytes, Per cu. mm.	Diagnosis		Course
	Age	Sex		Preoperative	Postoperative	
Johnson, 1932	63	M	15,400	Acute appendicitis	Hemorrhagic infarct of omentum	Recovered
Pines and Rabinovitch, 1940	63	M	12,400	Acute appendicitis	Infarct of omentum	Recovered
	53	F	10,000	Acute appendicitis	Infarct of omentum	Recovered
	40	M	18,000	Acute appendicitis	Infarct of omentum	Recovered
	52	M	13,500	Acute appendicitis	Infarct of omentum	Recovered
	37	M	9,800	Acute appendicitis	Infarct of omentum	Recovered
	47	F	9,000	Acute appendicitis	Infarct of omentum	Recovered
Bang-Dietrichson, 1941	46	F	Not recorded	Acute appendicitis	Hemorrhagic infarct of omentum	Recovered
Totten, 1942	27	M	Not recorded	Acute appendicitis	Hemorrhagic infarct of omentum	Recovered
	29	M	15,500	Perforated duodenal ulcer or perforated acute appendicitis	Hemorrhagic infarct of omentum	Recovered
Durando, 1945	58	F	Not recorded	Acute appendicitis	Hemorrhagic infarct of omentum	Recovered
MacKenzie and Small, 1946	29	M	17,620	Acute appendicitis	Hemorrhagic infarct of omentum	Recovered
Present author	40	F	13,800	Acute appendicitis Pregnancy	Infarct of omentum Pregnancy	Recovered

mary hemorrhagic infarction in the greater omentum, was treated successfully by resection of the infarcted portion. His patient had had heart disease for many years, which may have been a contributory factor in the formation of a thrombus.

Schottenfeld and Rubenstein reported a case in which acute abdominal pain developed in a seven-year-old boy three days after he had sustained a kick to the abdomen by a playmate. This boy was thought to have acute suppurative appendicitis, but surgical exploration revealed a hemorrhagic omentum, with infarction of a portion of it. Uneventful recovery followed resection of the diseased portion of the omentum. In this case the hemorrhagic infarction clearly was secondary to trauma, so that inclusion of the case in this series of cases of idiopathic segmental infarction is open to question.

Totten reported two cases in which primary segmental infarction of the greater omentum was clear-cut and unaccompanied by complicating factors. The condition of one of his patients had been diagnosed as "acute appendicitis" and that of the other as either "subacute perforation of a peptic ulcer" or "acute appendicitis with perforation and local peritonitis." At operation each patient was found to have an infarct of a localized, distal segment of the greater omentum, without a coincident intraperitoneal pathologic condition. The author pointed out that in these cases the omentum was thick and fatty, a condition which in his experience is in marked contrast to that in the majority of cases of omental torsion, in which he had found the omentum to be thin, with a scanty amount of fat. He offered as a possible explanation of the cause of this condition the fact that the strain on the thin-walled veins between the stomach and omentum is increased at the time of vascular congestion incident to the ingestion of a full meal. During this period, additional strain from increased intra-abdominal tension, incident to straining, coughing, sneezing or lifting, may be sufficient to cause primary rupture of the dependent veins of the omentum, with hemorrhagic extravasation and secondary thrombosis. In support of this thesis, he said that one of his patients gave a history of heavy work in the handling of boxes weighing approximately 120 pounds (54.4 kg.) shortly after the noon meal and just prior to the onset of his abdominal pain.

Durando has reported a case of apparently authentic segmental infarction in which the patient recovered uneventfully after surgical resection of the involved segment of omentum. This author likewise pointed out the similarity of features of infarction of the greater omentum to those of acute appendicitis, and in respect to the former lesion, stressed the benign course leading to recovery after resection of the involved portion of omentum.

In 1946, MacKenzie and Small reported the most recently published case of this condition.

Their patient was a twenty-nine-year-old white man in whom generalized abdominal pain developed after the ingestion of 1 pound of cheese. Diarrhea first developed, and was followed by localized pain in the right lower quadrant of the abdomen. This pain later became more severe in the right upper abdominal quadrant. A diagnosis of "acute appendicitis" was made. At operation the appendix was found to be normal, but a large hemorrhagic necrotic mass, 11 by 7 by 4 cm., involving the right terminal portion of the greater omentum, was encountered. This exhibited venous thrombosis, with segmental infarction of the vessels, on microscopic study. The authors pointed out that this condition must be borne in mind when observations of the appendix do not explain the clinical symptoms present. They considered constipation to be of frequent occurrence among such patients, whom they described as being "bowel conscious."

Report of a Case

A white housewife, forty years old, was referred to the clinic on January 10, 1943, because of abdominal pain in the right lower quadrant of forty-eight hours' duration. Review of her history disclosed that she had been married for twenty years and had been pregnant three times and delivered normally in each instance. She had made one previous visit to the clinic in the preceding year, at which time a diagnosis of "cardiospasm with moderate dilatation of the esophagus" had been made and dilatation of the cardia had been carried out. Her menstrual history was characterized by regular periods with a twenty-one day interval, and her last menstrual period had occurred three months before the onset of the present illness. The family history was irrelevant to her condition.

Two days before the patient's entry, abdominal pain had developed in the right lower quadrant whenever the patient arose. This pain was constant, nonradiating, and was not accompanied by nausea. The pain persisted throughout the day, although the patient was ambulant, her appetite was good, and her distress was not too annoying. During the night of the date of onset of the pain she occasionally was awakened by the abdominal pain. On the next day the abdominal pain continued to be steady, sharp and nonradiating, in the right lower quadrant of the abdomen. The patient had regular bowel movements and had noted no other symptoms except that the pain seemed to be worse on motion of the body. On the day of her admission the patient had been seen by her local physician, who had made a diagnosis of "acute appendicitis" and had referred her to the clinic for treatment.

Physical examination revealed a well-developed and well-nourished white woman who was apprehensive and crying. Her systolic blood pressure was 128 mm. of mercury; the diastolic pressure was 76 mm. of mercury. Her pulse rate was 90 beats per minute. Her temperature at admission was recorded as being 98.6° F. (37° C.) Abdominal examination disclosed point tenderness of grade 2 (on the basis of 1 to 4, in which 4 is most severe) in the right lower abdominal quadrant, and voluntary spasm and rebound in the same area. Vaginal examination revealed the cervix to be soft and freely movable. The uterus was felt to be the size of a uterus two to three months pregnant. The adnexa appeared to be normal. Rectal examination revealed slight tenderness of the right lateral wall. Results of the remainder of the examination were within normal limits.

Examination of a catheterized specimen of urine revealed it to have a specific gravity of 1.016. Albuminuria of grade 1 (on a basis of 1 to 4) was present. Microscopic examination of the sediment of a specimen of centrifuged urine disclosed an occasional erythrocyte and 10 leukocytes per field, under low-power magnification. White blood cells numbered 13,800 per cubic millimeter; 82 per cent were polymorphonuclear neutrophils, 16 per cent were lymphocytes, 1 per cent were monocytes and 1 per cent were eosinophils.

A preoperative diagnosis of probable atypical acute appendicitis as well as intra-uterine pregnancy was made. Surgical exploration was advised and accepted.

Abdominal exploration, through a primary lower right rectus incision, was carried out on the day of the patient's admission. Spinal anesthesia with procaine hydrochloride was employed. A portion of the greater omentum, 3 by 3 cm., was found to be the site of an acute inflammatory reaction, and was excised. The remainder of the abdominal exploration disclosed nothing significant except for the enlarged uterus, which extended well above the symphysis pubis, was rather soft, and indicated a normal pregnancy. The appendix was removed and the abdomen was then closed. Five grams of crystalline sulfathiazole was left in the peritoneal cavity.

Microscopic examination of the excised omental tissue disclosed infarcted omentum. The appendix showed signs of chronic inflammation.

Convalescence was uneventful. The patient was dismissed from the hospital on the twelfth postoperative day, at which time she had no complaints.

Comment

Review of the cases of primary idiopathic segmental infarction of the greater omentum in the literature does not reveal any significant features which might be of aid in a definite, preoperative differential diagnosis between the lesion and acute appendicitis or other acute intra-abdominal lesions. Undoubtedly, this type of infarction of the omentum occurs more frequently than is indicated by the number of reported cases. In many instances it probably is not recognized because of the inability of the surgeon to carry out thorough exploration of the abdomen when a small McBurney incision has been made with the expectation that the pathologic process is situated in

the appendix or terminal portion of the ileum. It is not unlikely that a small percentage of patients thought to have "acute appendicitis" which is atypical and consequently is treated by medical measures, in reality have infarction of the greater omentum. We wish to add our voice to that of others who have suggested that this pathologic entity should be considered whenever surgical exploration fails to reveal pathologic changes in the appendix or other suspected organ or structure to account for the clinical symptoms, and that the omentum be inspected for evidence of a lesion or lesions which might explain such symptoms.

The course of infarction of the greater omentum not treated surgically undoubtedly is benign. When operation is not performed, the omentum probably adheres to adjacent organs or structures. Such early, fine adhesions between omentum, parietal peritoneum and bowel have been found at operation in cases of segmental infarction of the greater omentum.

Summary

A case of primary idiopathic segmental infarction of the greater omentum has been presented, and twelve previously reported cases in the literature have been reviewed. Apparently there are no diagnostic criteria by which a preoperative diagnosis of the lesion can be definitely made. All the patients in reported cases have recovered uneventfully after excision of the infarcted segment of omentum. Recognition of this pathologic entity probably would be more frequent if the omentum were thoroughly inspected in all cases in which sufficient pathologic evidence to account for the clinical symptoms has not been clearly demonstrable.

EPITHELIOMAS OF THE LOWER LIP

(Continued from Page 986)

factory end results are to be anticipated in those cases in which no involvement of the nodes is demonstrable at the time of their removal.

Dissection of the cervical nodes is hardly justifiable if the primary lesion is graded 4. Under these circumstances, much more can be accomplished by roentgen and radium treatment to the neck than by dissection of the cervical nodes. As a matter of fact, many lesions of Grade 4 malignancy on the lips can be completely cured by irradiation if they have not produced generalized metastasis.

Dissection of the cervical nodes is undesirable for patients of advanced age, in poor general physical condition or with too extensive involvement of the nodes in the neck. Under these circumstances, irradiation may be considered. It is true, of course, that metastasis is less likely to develop in elderly individuals and, consequently, the removal of cervical nodes as a prophylactic measure is not advocated for patients who are more than seventy years of age. When involvement of the cervical nodes is so extensive as to contraindicate dissection of the cervical nodes, irradiation is recommended as a palliative rather than a curative measure.

PENICILLIN AND STREPTOMYCIN AEROSOL THERAPY FOR CHRONIC BRONCHIECTASIS

ARTHUR M. OLSEN, M.D., F.A.C.P.
Rochester, Minnesota

BRONCHIECTASIS is a serious disease which merits the attention of all physicians. Since it often goes unrecognized in its early phases, a chronic cough always should be investigated carefully. A positive diagnosis of bronchiectasis can be made only after complete bronchographic studies, for the symptoms and even the roentgenogram of the chest cannot be relied on in making the diagnosis.

In chronic bronchiectasis, the smaller bronchial tubes in the periphery of the pulmonary segments are dilated permanently. Cure can be effected only by removal of the segments of the lung that are involved. The symptoms of bronchiectasis are those of its complications. Secretions which accumulate in the dilated bronchi become infected and produce a chronic inflammatory process in the walls of these bronchi. As a rule, the infection associated with bronchiectasis is non-specific rather than specific. Thus, many types of bacteria are found in the secretions which constantly form in these bronchi. The common bacteria which can be demonstrated in the sputum of these patients are listed in Table I.

The nonsurgical treatment of bronchiectasis includes the effective drainage of the infected secretions and the destruction of the bacteria in the secretions and in the bronchial mucosa. Postural drainage is a time-honored method of helping to eliminate purulent secretions from the bronchial tree and should be employed in every case of bronchiectasis. Bronchoscopic examination is of particular value in the exclusion of organic obstruction in the larger bronchi and temporarily helps the patient in his struggle to rid himself of the noxious secretions which constantly form in the infected bronchi. Antibacterial agents have assumed a definite place in the management of infected bronchiectasis. The oral and parenteral administration of sulfonamides and antibiotic preparations has proved of limited value in the reduction of the volume of infected bronchial secretions but certainly has aided in the prevention of complications following pulmonary resection for bronchiectasis. In recent months it has been demonstrated that the introduction of antibiotic preparations into the tracheobronchial tree is the most effective means of combating infection associated with bronchiectasis.

TABLE I. COMMON PATHOGENIC BACTERIA FOUND IN BRONCHIECTATIC SECRETIONS

Gram Positive	Gram Negative
Pneumococcus	Escherichia coli
Streptococcus	Hemophilus influenzae
Hemolytic type	Aerobacter aerogenes
Nonhemolytic type	Klebsiella
Staphylococcus	Pseudomonas aeruginosa
Micrococcus	Proteus

Methods of Administration of Antibiotic Agents

The two principal methods by which solutions of penicillin or streptomycin can be introduced into the bronchi are as follows: Solutions may be instilled directly into the trachea through the bronchoscope, through a tracheal catheter, or by supraglottic instillation with a syringe and tracheal cannula. The other method consists in having the patient inhale a mist or aerosol of the solution. Both of these methods have their advantages and disadvantages.

In our experience, direct instillation of antibiotic preparations into the bronchial tree is accomplished most satisfactorily by the supraglottic method. It usually is necessary to introduce 1 or 2 c.c. of a 5 per cent solution of cocaine into the trachea with a syringe and tracheal cannula. This procedure will provide sufficient local anesthesia to permit the patient to retain the solutions that will be instilled. Penicillin sodium is dissolved in physiologic saline solution in a concentration of 20,000 units per cubic centimeter, and 5 or 10 c.c. of this solution is instilled slowly. When streptomycin hydrochloride is used, it is dissolved in physiologic saline solution in a concentration of 0.1 gm. per cubic centimeter and, again, 5 to 10 c.c. may be employed. If the patient will lean either to the right or left side as he sits in his chair, the solution may be instilled into either side of the bronchial tree. If penicillin sodium and streptomycin hydrochloride are used, the solutions may be mixed and given at one time.

From the Division of Medicine, Mayo Clinic, Rochester, Minnesota.
Read at the meeting of the American College of Physicians, Chicago, Illinois, May 1, 1947.

Supraglottic instillations may be given daily for many days. The success of this form of treatment depends on the ability of the patient to cooperate. It is desirable that instillations be given when the patient's stomach is empty. Postural drainage exercises should be carried out before each treatment. This method of treatment is much more effective when the patient is able to retain the solution for several hours than when he can keep it only a short time. Many patients are able to retain the solution without the benefit of local anesthesia.

Supraglottic instillations require some expertness on the part of the physician as well as the cooperation of the patient. A large dose of penicillin or streptomycin or both may be given in a short time. For patients who have a large volume of purulent bronchial secretion, the supraglottic method has been effective, especially when employed as an adjunct to aerosol therapy. Disadvantages of the method are the frequent use of cocaine or a similar agent to produce local anesthesia and the fact that some patients are completely incapable of retaining the solutions.

Administration of nebulized antibiotic agents has been employed in nearly all of the cases of bronchiectasis treated at the Mayo Clinic. We have used either the Vaponefrin or DeVilbiss No. 40 nebulizer. Although we have tried the nebulizers equipped with large condensing bulbs or with rebreathing bags, we have returned almost invariably to the standard nebulizer because it is convenient and easy to handle. For hospital practice we have continued to use compressed oxygen as a source of positive pressure. For home treatment many patients have obtained small electric motors and air compressors or have used foot-operated air pumps.

We have been using penicillin sodium in concentrations ranging from 10,000 to 25,000 units per cubic centimeter. We usually give 200,000 to 400,000 units of penicillin daily. We have continued to use streptomycin only in cases in which Gram-negative organisms predominate in the sputum after a period of treatment with penicillin alone. In general, we find it desirable to mix streptomycin hydrochloride with penicillin sodium. Thus 200,000 to 400,000 units of penicillin and 0.5 to 1.0 gm. of streptomycin are dissolved in 16 to 20 c.c. of physiologic saline solution. Patients can nebulize 1 c.c. of solution in ten or fifteen minutes. Hospital patients are asked to nebulize 2 c.c. every hour for eight or ten hours each day.

Preoperative Management of Bronchiectasis

Bronchoscopic examination and complete bronchographic studies are carried out in all our cases of bronchiectasis in which pulmonary resection is considered. Before lobectomy or pneumonectomy is performed in the suitable cases, it is desirable that most of the iodized oil retained in the healthy lung tissue after bronchographic studies be coughed up or absorbed. Whenever possible, nebulization therapy is instituted in the waiting period. Penicillin is used routinely, and streptomycin is used in cases in which Gram-negative bacteria are found in the sputum. Daily supraglottic instillations are carried out in some cases. The length of preoperative treatment depends on the volume of purulent secretions and the amount of lung tissue to be resected. Patients who have bilateral involvement are given a much longer course of preoperative treatment. In the usual case in which bronchiectasis is confined to one lobe, five to seven days of preoperative treatment is adequate. In the forty-eight hours prior to operation our patients now receive large doses of penicillin by intramuscular injection. Postural drainage exercises are employed in all cases.

It has been our definite impression that the preparation of patients for lobectomy with penicillin aerosol has been most helpful in preventing postoperative complications. Although in occasional cases empyema occurs, the incidence of complications following pulmonary resection for bronchiectasis has been very low.

Nonsurgical Management of Bronchiectasis

Unfortunately, many patients who have bronchiectasis are not suitable candidates for pulmonary resection. These patients often are the ones who are most desperately in need of help. Frequently they are dyspneic and chronically ill and often have disease of the accessory nasal sinuses. Their sputum often has a foul odor, and they are virtual outcasts from society.

No treatment will cure these individuals of their bronchiectasis. From experience we know that sufficient rest and good nutrition, a favorable climate and regular postural drainage will help them to control the bronchorrhea. Aerosol therapy has been of great benefit in a good many of these cases. However, a much longer period of in-

tensive treatment is required than in the preoperative cases. Most of our patients have been hospitalized for their initial course of treatment, which may last from two to six weeks. Inhalation treatment with penicillin is started on admission. Stains and cultures of the sputum are made twice a week. An accurate chart of the daily volume of sputum is kept, and notations are made of character and odor of the secretions. Postural drainage is carried out before each meal and at bedtime. After a few days of treatment with penicillin, Gram-positive bacteria begin to disappear from the sputum and Gram-negative organisms may predominate. When this occurs, streptomycin is added to the solution. If a marked reduction in the amount of sputum is not obtained by this method of treatment, daily supraglottic instillations of penicillin and streptomycin are begun. The supraglottic instillations have been particularly effective in cases in which bronchorrhea is excessive and in which pulmonary fibrosis and emphysema are associated. When the daily volume of secretions has been reduced by 75 per cent or more, the patient is allowed to return home. He is asked to continue treatment at home, using 100,000 units of penicillin in 5 c.c. of physiologic saline solution each day. The patient regulates his further treatment by the amount of trouble he is having. Some patients control their symptoms by taking treatment two or three days a week. Others are able to go long periods without any treatment.

Results of Treatment

Arbitrarily, my colleagues and I have regarded response to treatment as satisfactory if the quantity of bronchial secretion is reduced by 75 per cent or more. In about 60 per cent of seventy-five cases of nonsurgical bilateral bronchiectasis, the use of penicillin aerosol alone has produced satisfactory results. Streptomycin has been used in conjunction with penicillin in many cases in which Gram-negative bacteria appeared in the sputum. Penicillin and streptomycin aerosol therapy have produced satisfactory results in 90 per cent of cases. Many of the patients received supraglottic instillations to supplement aerosol treatment.

After cessation of treatment, recurrences of bronchorrhea are common, especially after acute upper respiratory infections. Obviously, this aerosol treatment does not cure bronchiectasis, but it has made the lives of a good many patients comfortable. In a few of our cases, symptoms have recurred and have not responded to further intensive treatment. In such cases we have been able to demonstrate bacteria in the sputum which are resistant to penicillin and streptomycin. Streptococcus faecalis has been a difficult organism to control. One patient has had an infection due to a type of colon bacillus which was resistant to streptomycin. It is our impression that Gram-negative bacteria are more likely to become resistant to streptomycin than are Gram-positive bacteria to penicillin. In some instances we have given a 5 per cent solution of sodium sulfathiazole by nebulization with apparent benefit. Fungus organisms found in bronchiectatic secretions are not sensitive to penicillin or streptomycin. However, such organisms seem to disappear as the bacterial invasion is checked.

Comment

Undoubtedly, many improvements will be made in this program outlined for the management of bronchiectasis. The use of vasoconstrictor solutions, such as neosynephrine hydrochloride, appears to have a place. Some authorities have used solutions of hydrogen peroxide as the medium for giving penicillin by nebulization. Penicillin has been mixed with iodized oil for supraglottic instillations. Oronasal masks have been employed, and an automatic demand valve of the Emerson type has been used to replace the finger-operated Y tube. Plastocele hoods have been designed for giving aerosols to infants and children, and aerosols have been produced in sealed rooms or compartments. New and more efficient nebulizers undoubtedly will be manufactured, and equipment for nebulization therapy certainly will be simplified and made more readily available.

Aerosol therapy and the intrabronchial use of antibiotics and other drugs have a definite place in the treatment of bronchiectasis. However, it must be remembered that a complication of bronchiectasis rather than the primary disease is being treated. The results of aerosol therapy are likely to be temporary, and continued or intermittent treatment is essential if improvement is to be maintained. The patient must be reminded that he is still subject to the hazards of a serious bronchial disease.

CLINICAL-PATHOLOGICAL CONFERENCE

A REVIEW OF 100 CASES OF RENAL FAILURE

WILLIAM D. COVENTRY, M.D., and ARTHUR H. WELLS, M.D.
Duluth, Minnesota

These 100 case studies were selected from 3,400 necropsy records on the basis of renal failure occurring as a most important factor in the causes of death. All cases of extra renal azotemia were excluded. The material represents the experience of twelve and a half years and 107,000 admissions to this general hospital. We have used a modification of E. T. Bell's classification[1] of renal diseases, so that the cases will be divided into eight groups: malformations, obstructions of the urinary tract with hydronephrosis and without pyelonephritis, pyelonephritis, glomerular nephritis, tubular diseases, vascular diseases, metabolic disorders, and tumors of the kidney.

Malformations

There was one case of fatal renal insufficiency in each of the congenital diseases: renal agenesis, cystic disease, uretheral valve, and congenital stenosis of the proximal ureteral orifice.

Of particular interest in this group was the case[2] of a boy, aged three and one-half months, who had had mild digestive disturbances for one month. He was considered seriously ill with vomiting and weakness for only a few days before he expired with a blood urea value of 214 and a creatinine level of 5.3 mg. per cent. The necropsy revealed two semilunar valves in the lower prostatic urethera, with extreme dilatation of the proximal urinary tract and resultant advanced pressure atrophy of the kidneys. In contrast, is the seventy-three-year-old woman who expired in uremia as the result of severe bilateral congenital stenosis of the proximal ureteral orifices with bilateral pyelonephritis.

Hydronephrosis Without Pyelonephritis

In the group of renal insufficiency due to hydronephrosis without the complication of kidney infection there were five cases. One each of the diseases, prostatic, bladder and pancreatic carcinoma, prostatic hypertrophy and prolapse of the uterus, were represented.

The case with the prolapsed uterus in a seventy-two-year-old housewife is in some respects the most interesting of the entire study. The multiparus woman had known of her prolapse for thirty years. It extended 9 inches below the vulva, and when returned to its proper position by her physician, Dr. Elizabeth Bagley, there was a spontaneous gush of a great volume of urine. She was *in extremus* when admitted and expired within twelve hours. The necropsy revealed a grade IV hydronephrosis with mere shells of kidneys remaining. The bilateral hydroureter began a few centimeters above the urinary bladder on each side.

Pyelonephritis

The cases with interstitial kidney infections leading to renal failure were divided into those with urinary tract obstruction, numbering twenty-six, those without urinary passage obstruction eight, and those with tuberculosis three (Table I).

TABLE I. DISEASES OF INTERSTITIAL TISSUE—PYELONEPHRITIS

A.	Pyelonephritis with urinary obstruction	
	1. Urethral stricture	1
	2. Prostatic hypertrophy	11
	3. Prostatic cancer	1
	4. Bladder cancer	4
	5. Cervix cancer	5
B.	Pyelonephritis without urinary obstruction	8
C.	Specific infections	
	1. Tuberculosis	3

In the first group with obstruction of the urinary tract were eleven patients with benign prostatic hypertrophy, all of whom were over seventy years of age except for three who were sixty-three, sixty-seven and sixty-nine years old. The creatinine level at death averaged 4.7 mg. per cent. There was no significant systolic or disastolic hypertension present in these patients.

A review of the eight cases of pyelonephritis without urinary tract obstruction revealed all the patients under the age of seventy years except for three who were seventy-six, seventy-seven, and seventy years old. The youngest was forty-seven. Very high creatinine values were reached before death, averaging 12.3 mg. per cent. There was no significant hypertension in this group. Most of these patients had 100 pus cells or more per high power field in their urinary sediment. A correct antermotem diagnosis was not made in a single case, possibly because of the many infectious complications found in these pyelonephritic patients.

There were twenty cases with bronchopneumonia among the twenty-four patients in the pyelonephritic series, while among the seventy-six patients of all the other causes of renal failure there were only seventeen with bronchopneumonia. Of the other serious infectious complications besides pneumonia, there were twenty in the entire 100 cases studied. Seventeen of these occurred in the pyelonephritic series. Uremic pericarditis was not considered infectious. It was fairly equally divided in the various groups and was found in fifteen cases.

From the Departments of Pathology and Medicine, St. Luke's Hospital, Duluth, Minnesota.

Glomerular Diseases

There were sixteen cases of glomerular nephritis divided between acute (four), subacute (two), and chronic (ten) (Table II). Our classification varies from that of Bell's in that we did not divide the glomerular nephritis cases into nephritic and nephrotic types. We did not have a single case of so-called lipoid nephrosis, in the more widely accepted sense of the term. There were thirteen of the sixteen cases of glomerular nephritis with severe edema, while in the entire study of eighty-four other cases there were only fifteen additional patients with severe edema of tissues at the time of death. None of our four cases of acute glomerular nephritis had hypertension. Francis Murphy, however, finds that 75 per cent in a large series of acute glomerular nephritis cases develop hypertension.

TABLE II. GLOMERULAR DISEASES

A.	Glomerular nephritis	
	1. Acute	4
	2. Subacute	2
	3. Chronic	10
B.	Lipoid nephrosis	none
C.	Amyloid disease	2
D.	Focal embolic nephritis	1

Nine of the patients with chronic glomerular nephritis were under sixty years of age, while the tenth was sixty-eight. All of the patients with chronic glomerular nephritis had moderate hypertention, and in only three the systolic pressure was over 200 mm. mercury. Only five of the hearts weighed over 400 grams, and the heaviest was 595 grams. The kidneys of three patients were 150 grams each, or more, while all the remainder were severely reduced in weight. Bell found no relationship between the size of the kidneys and the size of the heart, or between the size of the kidneys and the blood pressure, in patients dying with chronic glomerular nephritis. The average last creatinine value in our group was 6.5 mg. per cent. The urinary sediment showed not more than 0 to 50 red blood cells and 0 to 50 white blood cells per high power field.

Tubular Disease

We found one case each of bichloride and sulfathiazol injury of the kidneys leading to death. The latter occurred when the drug was first introduced for general use and before the importance of maintaining maximal fluid intake, alkalinization, and observation of the white blood cell count and the urine sediment were fully appreciated. The great wonder is that we have not had more deaths, considering the number of patients receiving sulfonamide drugs. Two additional patients in the tubular disease group expired as the result of plugging of tubules of the kidneys by casts of unknown nature.

Vascular System Disease

Our largest single group of patients in the study was that of the arteriolosclerotic series (Table III), which totaled twenty-four cases. Three patients died primarily as the result of arteriosclerotic nephritis. Five had diabetes mellitus with renal failure. The one patient with bilateral cortical necrosis was a forty-nine-year-old woman who expired after five days of anuria developing immediately following a spontaneous delivery of a normal child.[3]

TABLE III. BLOOD VASCULAR SYSTEM

A.	Arteriosclerotic (large artery)	3
B.	Arteriolosclerotic (small arteries)	24
C.	Diabetes mellitus	5
D.	Infarction cortical necrosis	1

A review of the large arteriolosclerotic series reveals a number of interesting points. These patients died at all ages between twenty-two and ninety years. All had severe systolic and diastolic hypertension except for five patients who had debilitating complications. The remarkably large hearts weighed from 500 to 760 grams except for two weighing 305 and 350 grams. In Bell's patients, 95.5 per cent of the male hearts weighed over 400 grams, and 83 per cent of the hearts of females were over this weight. Eighty-two per cent of Bell's large series had systolic pressures over 200 mm. mercury. The kidneys in our series averaged below 150 grams each in weight and ranged from 35 to 170 grams. The average creatinine value of our series was 7.0 mg. per cent at the time of death.

Five patients with Kimmelstiel-Wilson syndrome (diabetes mellitus, hypertension, 4-plus albuminuria and sclerotic changes in small arteries and glomerular capillaries) expired as the result of renal insufficiency. Thirty-three of 149 cases of diabetes mellitus in Bell's series died in uremia; of these, only eighteen had structural changes in the kidneys.

Metabolic Disorders and Neoplasms

There was only one death in this study due to pyelonephritis complicating renal calculi. The cause of the calculi was not apparent.

The last unusual case was that of a sixty-three-year-old male with a Wilms tumor of the right kidney, which metastasized to the hilar region of the left kidney, eventually terminating in uremia.

Summary

A brief review of 100 cases of renal failure due to kidney diseases culled from 3,400 necropsies is presented.

Several unusual and rare conditions, including uretheral valves, congenital ureteral orifice stenosis, uterine prolapse with extreme bilateral hydronephrosis, bilateral cortical necrosis and Wilms tumor in a sixty-three-year-old male, were found in the study.

The largest single group (24 per cent), with arteriolosclerosis, had outstanding high blood pressures and huge hearts. Five diabetic patients expired because of sclerotic changes in small arteries and capillaries of the kidneys. Renal failure resulted from sclerosis of the large renal arteries in three patients.

Thirteen of the sixteen patients with glomerular nephritis had severe edema at the time of death, while there were only fifteen additional patients with severe

(Continued on Page 1032)

History of Medicine In Minnesota

NOTES ON THE HISTORY OF MEDICINE IN COTTONWOOD COUNTY

L. L. SOGGE, M.D.
Windom, Minnesota

(Continued from August issue)

Dr. William David Moir Beadie (1874-1941) was born of Scottish parents in Toronto, Canada, on June 15, 1874, and lived there until his family moved to Montreal when he was thirteen years old. He was graduated in medicine from McGill University in 1900 and practiced medicine in Windom, Minnesota, from 1901 to 1910, moving then to Saint Paul where he remained in general practice until, in 1917, he became superintendent of Pokegama Sanatorium. From Pokegama he went to Cannon Falls to take over direction of the Mineral Springs institution in 1923.

In 1903 he married Miss Elizabeth McGregor of Windom. To this union was born a son, William McGregor Beadie, who now resides in Saint Paul with his two sons, David Moir Beadie and William Merrill Beadie.

During the period of his practice in Saint Paul, Dr. Beadie was a member of the medical staffs of the University Hospital, the City and County Hospital, the Gillette State Hospital and the Jean Martin Brown Home for Orphans. He was also a member of the Ramsey County Medical Society until his death and of the Minnesota State Medical Association, the American Medical Association, the Minnesota and the American Trudeau Societies and the National Tuberculosis Association.

When Dr. Beadie took over the direction of the Mineral Springs Sanatorium at Cannon Falls—the institution which absorbed all of his interest for seventeen years—he found an institution of twenty-five beds, a limited untrained personnel, small equipment and supported by only three counties. When he retired because of ill health on January 1, 1941, he left a completely modern institution of 110 beds, staffed by trained personnel, supported by six counties and ranking third among tuberculosis institutions of the state. The work and planning and devotion entailed in such an achievement was clearly hard and exhausting.

The growth of the Mineral Springs Sanatorium under Dr. Beadie's direction was remarkable. There is a modern four-story building now, in place of the original twenty-five bed institution, with its own power plant, concrete water reservoir, nurses home, laundry and house for the superintendent. Modern x-ray equipment and a well-equipped laboratory have been added. The institution is staffed with registered nurses—indeed it was the first tuberculosis institution of the state to employ only registered nurses. Patients of the institution have radio earphones at each bedside. They publish their own monthly magazine, *The Sanscript,* which, incidentally, devoted an entire issue to praise of Dr. Beadie and his work when he retired from office. They have a Sanatorium book club to supplement the permanent institution library

and they are encouraged to do all kinds of suitable hand work and occupational therapy.

The Sanatorium also has a full-time field nurse as the result of Dr. Beadie's efforts, and clinics are held throughout the district under direction of the superintendent. The district which began with Goodhue, Rice and Dakota Counties, now includes Olmsted, Mower, and Freeborn, all of which assist in support of the institution.

Obviously, Dr. Beadie made a far-reaching contribution to the control of tuberculosis in Minnesota. He devoted the major part of his professional life to its prevention and cure and led in the statewide sanatorium movement which has worked so vigorously in Minnesota for isolation for all active cases of tuberculosis and for periodic examinations of all who have been in contact with active disease.

When ill health forced him to retire from the Sanatorium in 1941, Dr. Beadie went back to Windom where he first started the practice of medicine forty years ago, and where Miss Margaret McGregor, sister of Mrs. Beadie, still lives. His death on February 7, 1941 cut short a plan to build a home and live there in quiet and retirement.

Affiliate membership in the Minnesota State Medical Association to which Dr. Beadie became eligible at his retirement, was not awarded until after his death. The permanent bronze membership card, now awarded to all affiliates, was presented by order of the Council to his family.

Dr. Beadie was a gentleman, a distinguished physician, and a recognized authority on the care and control of tuberculosis in Minnesota.

Among his fellow physicians he will long be remembered as a beloved colleague who upheld the best and highest ideals of his profession and as a leader in the development of our fine system for care of the tuberculous sick in Minnesota. Among his hundreds of patients at Mineral Springs Sanatorium he will be remembered as a friend who never failed them in kindness and generosity and who brought health and hope to many who otherwise would have died unaided.

In the passing of Dr. Beadie, the Minnesota State Medical Association as well as the Ramsey County Medical Society of which he was a member for so many years, lost one of its finest exemplars of devotion to duty and to the highest ideals of medical practice.

John H. Tilford (1841-1899) was for many years, from 1878, one of the leading and most successful physicians and surgeons of Windom, Cottonwood County, Minnesota. The place of his nativity is found in Jefferson County, Indiana, where he was born on November 28, 1841.

The parents of Dr. Tilford were Joseph M. Tilford and Mary A. Maxwell Tilford, natives respectively of Kentucky and Indiana. Joseph M. Tilford left Kentucky when about twenty-one years of age and settled in Madison, Indiana, where he engaged in the cabinet making business. He carried on an extensive trade until 1851, when he removed to the city of Indianapolis, where he engaged in the same business. In 1856 he sold out and purchased the *Indiana State Journal,* of which he became the publisher. When the hard times came, in 1870, his business had to be abruptly closed, and he retired to private life.

John H. Tilford, one of a family of nine children, received early educational advantages of a high order. After completing a course in the district schools, he went, at the age of eighteen years, to Northwestern Christian College in Indianapolis, where he was a student several years. He then began the

study of medicine in Indianapolis with Drs. Jamison and Funkhouser, with whom he continued for three years. He next attended medical lectures at the University of Michigan, Ann Arbor, during the winter of 1861-1862. In the spring of 1862 he accepted an invitation from his old preceptor to enter the city hospital of Indianapolis to assist in caring for the sick and disabled.

In August, 1862, Dr. Tilford was commissioned as assistant surgeon of the Seventy-ninth Indiana Regiment of Volunteer Infantry, and with a portion of the regiment he went to Louisville, Kentucky. Throughout the war he served as military surgeon, in Kentucky, Tennessee, Georgia and Alabama; always on duty, during three years he never left his command.

On being mustered out of the service, he returned to Indianapolis. During the winter of 1865-1866 he attended a course of lectures at Bellevue Hospital Medical College. He then returned again to Indianapolis, where he practiced medicine for one year. His next move was to Pittsborough, Hendricks County, Indiana, where he engaged in medical practice for nine years. During this time, in 1872, he was graduated from the Indiana Medical College. In 1878 he took an ad eundem degree in medicine from Butler University. On leaving Pittsborough, Dr. Tilford settled in Irvington, Marion County, Indiana.

In October, 1878, Dr. Tilford arrived in Windom, Minnesota. A man of excellent qualifications, highly educated, a master of the details of his profession, he built up in Windom a successful and lucrative practice, and he became a leading and influential member of the Minnesota State Medical Association. A constructive citizen who took an active part in public matters, he served as coroner of Cottonwood County and as a member of the board of his township and on the local school board. His numerous investments in various kinds of property were successful. On several lots that he purchased in the city he built an elegant residence and a well-equipped office.

Dr. Tilford was a member of the Republican Party. He belonged to the Masonic Lodge, the Independent Order of Odd Fellows and the Ancient Order of United Workmen, and the Grand Army of the Republic.

John H. Tilford was married in 1866 to Luna Meak, a native of Greenfield, Indiana. This lady possessed a superior education and was a graduate in music; she was an instructor in music for a number of years in Indianapolis, Noblesville and Greenfield, Indiana. Dr. and Mrs. Tilford had two children, Fred M. Tilford and Mattie R. Tilford. Dr. Tilford died in Windom on September 6, 1899.

Dr. Tilford and the late distinguished Dr. Harvey W. Wiley (1844-1930) were first cousins and good friends who corresponded regularly with each other. Dr. Wiley, a native of Kent, Indiana, was a son of Preston P. Wiley and Lucinda W. Maxwell Wiley.

Reminiscent comments have come from Dr. Tilford's daughter, Mattie (Mrs. William F. Sanger), of Windom:

> As a pioneer doctor, Dr. Tilford had some serious experiences. Though I was a small girl, I well remember a few, because I was impressed by my mother's deep concern and worry over the terrible blizzards we had in the winters then. There were no telephones, and many times my father would be gone for two or three days at a time. On one occasion, with a driver, he started out in a bad blizzard and became lost. Both men got out of the rig to look for tracks and both fell into an old cellar; they managed to crawl out, recover the team, and finally reach their destination. My father always depended much on his horses and thought a great deal of them; he felt that if he ever became hopelessly lost the horses would eventually get him to a farm house or would bring him home. Often, when roads were impassable, he was obliged to leave the team and walk home, and many times, although

he dressed as warmly as possible, with all he could carry, he reached home with icicles hanging from his eyelashes, nose and mustache, his cheeks frosted and also his feet. But whatever the weather conditions, if humanly possible, he never refused a call.

Frank Ressler Weiser (1865-1925) was born on November 10, 1865, at Sunbury, Pennsylvania. He was the son of Dr. George B. Weiser and Susan R. Weiser. His early education was secured in the public schools of Millersburg, Pennsylvania, and the Millersburg High School. He was graduated from the Philadelphia College of Pharmacy in 1888 and from the Jefferson College of Medicine in 1891.

Dr. Weiser practiced medicine for three years in Williamstown, Pennsylvania, from 1891 to 1894. On March 1, 1894, he was united in marriage with Miss Jeanette Schoch, and with his wife came to Windom, Minnesota, the same spring. He was licensed to practice medicine in the state in April, 1894. For thirty-one years he had an active part in the development and progress of his city, ever interested in all things that made for the betterment of the community.

Among his many responsible offices was that of councilor of the State Medical Association for the Second District of Minnesota. He was also a member of the Southwestern Minnesota Medical Society and of the American Medical Association. From January, 1911, to 1917, he was a member of the Minnesota State Board of Medical Examiners, serving as president in 1916. Dr. Weiser was interested in all forms of education; he was a member of the Windom board of education from 1915 to 1921, and served as clerk of the board for the last six years of that period. He was coroner of Cottonwood County several years. In politics he was an active Republican.

Among the most important of the doctor's interests outside of his professional and civic services was faithful and conscientious devotion to the Masonic fraternity. He was very active in the work of all the Masonic bodies in which he held membership, namely, Prudence Lodge No. 97, A. F. and A. M.; Windom Chapter No. 48, Royal Arch Masons; Windom Commandery, No. 39, Knights Templar; 32nd Degree Scottish Rite, Valley, Minneapolis; and Zuhrah Temple, Mystic Shrine. He was chairman of the advisory council of the Windom Chapter of DeMolay, which is sponsored by Masonry. He was also a member of the Royal Arcanum, Woodmen of the World, and the Woodmen Circle.

In early life, Dr. Weiser was baptized and confirmed in the Lutheran Church. In Windom he was affiliated with the Episcopal Church.

For several years toward the end of his life, Dr. Weiser was in poor health. In the autumn of 1924, because of an infection in his right foot, he was taken for examination to the Mayo Clinic at Rochester, where it became evident that amputation of his right leg was necessary in order to save his life. He recovered rapidly from the operation and again was active in his medical practice until early on the morning of May 22, 1925, when he was stricken suddenly with coronary thrombosis and died.

This beloved physician, loyal friend, good neighbor, kind and devoted husband, father and brother was survived by his wife, Jeanette Schoch Weiser; a son, Dr. Conrad Weiser, an Episcopal clergyman; a daughter, Helen, a schoolteacher; and two brothers, Dr. G. B. Weiser, of New Ulm, Minnesota, and William H. Weiser, of Millersburg, Pennsylvania.

NOTES ON MEDICINE IN FREEBORN COUNTY, 1857—1900

ANDREW GULLIXSON, M.D.
Albert Lea, Minnesota

This résumé begins with a modicum of early history of Freeborn County. This was included because the early hopes and aspirations of three of its pioneer doctors were quite intimately related to these beginnings. Again, in order to sense their "coming in and going out," a picture of the *tempora et mores* of 1857 is necessary. How could those gallant men, with no knowledge of the basic sciences of today, and with such limited armamentarium, wrap themselves around the heartstrings of their clientele and become so indispensable? Only one conclusion is evident. They possessed a deep regard for courageous duty and, with that, a profound sense of human understanding.

> *"When our earth came fresh and green and beautiful from a divine hand, the great command was to 'Take it, people it, and subdue it.'"*

By the time people came to redeem that implied pledge, Freeborn County was still green and beautiful, but it had grown rugged and hard to subdue. Thirty beautiful lakes were found, together with a thousand and one marshes and sloughs. About half the county was woodland, intermingled with innumerable small clearings ready and suitable for tilling. The wooded areas were largely of oak; but hard maple, ash, hickory, walnut, butternut, hackberry, and other varieties of trees, brush and berry bush, were also plentiful. Half was prairie land mingled with sloughs and marshlands. But it "promised winter and summer, day and night, seed time and harvest."

And so they came. Town-site operators had sawmills in operation in 1856. In 1857 people came in numbers. Splendid folk came from the East to establish homes and farms. Land speculators and boomers came in numbers to cheat and plunder until satisfied or apprehended, and then moved on to new fields. There was yet no bounty on wolves. The real back-breaking work of permanent settlement and home-building was largely accomplished by the immigrants who came in increasing numbers from 1857 on. Of these the Norwegians came first; then the Irish were the most numerous. Then came the Danes, then the Germans, and last, the Swedes. But Norway and Ireland, though immortalized in history and in song for their scenic grandeur and beauty, were lands where poverty, hunger, regimentation, neglect, and want were familiar companions. That is the reason why these two peoples were the easiest and most quickly to be assimilated into the very soul of their new-found and beloved America. Their early devotion and patriotism is exemplified in the New York Irish Brigade and the Fifteenth Norwegian Wisconsin Regiment in the Civil War.

That is also a reason why these two peoples are expert politicians, as is exemplified here in Minnesota history. But they all came, not only hungry for food, but hungry for freedom in this new land of promise, hungry for homes, hungry for schools for their children and for churches where they could gather in their respective congregations and worship in freedom according to the faiths of their fathers.

The early pioneer immigrants were, for the most part, a pious people. They were hard-working, clear-headed folk, who faced misfortune and dangers with courage, yet were sympathetic and tenderhearted. Their occasional deficiencies in some of the elegancies of social conduct were more than compensated for by their love and regard for humanity. Instances of questionable neighborly conduct would occur between the Norwegians and the Irish on St. Patrick's Day, March 17, and on Norway's Independence Day, May 17. But the next day these same neighbors would be helping each other in the fields. A prominent Norwegian

author described one of these May 17 celebrations, when the Irish lads exchanged compliments with the Norwegians, in essence as follows: The classes were assembled across the street from each other and the text books were the "mingled souls of wheat and corn," freely transferred from glass to lip. The urge finally came to cross the street and throw the Norwegian teacher out of his classroom. The meleé was lively and when a young Norwegian saw the battle going against his countrymen, he jumped down unsheathing his knife with the intention of assisting them in a larger way, but his teacher shouted to him, "Throw down your knife, my boy, we fight like Christian folk here in America."

Prior to March 4, 1855, Freeborn was still a part of Dodge County. On that date, the county limits were designated and the county was named Freeborn in honor of William Freeborn, a pioneer of Goodhue County. In March, 1856, one of the proprietors of Albert Lea townsite attended the territorial council in Saint Paul and succeeded in getting an act passed by which the organization of the county was perfected.

In November, 1856, the first election was held, and the entire voting population turned in forty-four votes. Post offices were established and mail facilities were provided by private enterprise. In March, 1857, the territorial legislature made provision for the county's independent government, and temporary officers were appointed. At the first general election in November, 1857, a full slate of officers was duly elected, with eleven precincts established, casting 664 votes. Dr. A. M. Burnham was elected coroner, but refused to qualify, and this office stood vacant for ten years. Dr. A. C. Wedge was elected to the Board of County Commissioners.

Besides the village of Albert Lea were Itasca, St. Nicholas, Shellrock, and Bancroft, standing as eager and potent contenders for the county seat. Two other villages in those early years (1856, 1857) were Moscow and Freeborn. Later, in 1869, with the coming of the Milwaukee Railroad, there were Hayward and Alden, and finally, in 1874, with the coming of the Minneapolis & St. Louis Railroad, were Emmons, Manchester, and Hartland. The first townsite operator in Albert Lea came in 1855. In 1856 appeared several well-educated, clean-cut, solid businessmen. In 1857, the first doctor, A. C. Wedge, came, as did also a good lawyer. Thus, Albert Lea was established by men of unusual energy and intellectual talents, and all of these men were used courageously and effectively through the guerilla warfare that later centered in the county seat fight. They were men of good character and judgment, steeped in the traditions of the town meetings of New England. They worked together with full cognizance of their responsibilities in building order out of chaos and they were willing and ready helpers to the immigrant pioneers in setting up their local governments. When the squatters' rights under the pre-emption laws were in jeopardy in President Buchanan's term of office, these men furnished an expense account and sent a delegate to Washington to help frustrate the plans of conniving land sharks, who were succeeding in their greedy acquisition of immigrant lands and homes.

The first white man to enter Freeborn County was Col. Albert Miller Lea with a detachment of 180 troops in 1835. An account of his observations reads as follows:

> "We passed through that beautiful region of lakes, open woods, and prairies in which the headwaters of the Blue Earth and Cedar rivers intertwine. We came upon an elevated promontory descending rather abruptly to the most beautiful lake we had ever seen. We stopped an hour at that exquisite spot and took a sketch of the lake."

The first white settler, Ole Guldbrandson, who came in 1853, was a Norwegian who settled in the vicinity of Shellrock. His log cabin of that date now stands

neglected on the county fair grounds. When he saw the smoke from nearby cabins in 1856 or 1857, he moved on. The order of settlement, after the hunter and trapper had passed on and the townsite operators had surveyed and organized for a year, was as follows: first came the businessmen, doctors, lawyers, and immigrant settlers; together with the land sharks, gamblers, and poachers of government timber and lands; and finally, when prospects looked good and business seemed to warrant it, came the railroads. The first railroad, the Milwaukee, came to Albert Lea in 1869, sixteen years after the first settler. Only one trail from the south, via St. Ansgar, Iowa, came to Freeborn County and it continued westward to Blue Earth. To get to Saint Paul it was necessary to walk to St. Ansgar, thence north to Austin, and thence north to, and along, the Mississippi River.

Settlements took over the wooded sections first, where the pioneers erected their log cabins near the many clearings, where the soil was open for the plow and the planter. The prairies were not settled as heavily until after 1869, when the railroad provided transportation for lumber and supplies. Many early prairie pioneers lived in sod houses. The first school house in Alden township was built of sod.

Dr. Frank A. Blackmer, just two months before he died, delivered a lively address before the Society of Territorial Pioneers in May, 1900. He came to Albert Lea with his parents, Dr. and Mrs. Franklin Blackmer, in 1856, and remembered well that when he was a lad of ten years, bread of cracked corn, tea of the dried tender leaves of red root, coffee from dried browned acorns, beets, roasted wheat, and dried and ground corn were the daily fare, and when, during the panic of 1857, men were dressed in the only available clothing, which was made of bed ticking, and looked like convicts. Dr. A. C. Wedge, president of the society, in introducing him said: "During those years our acquaintances were more than ordinary. The hardships made us neighbors, friends, and brothers. We realize now that we builded better than we knew in laying the foundations for a splendid civilization. It is well that the younger generation be reminded of the valuable services that were rendered and how much comfort they now enjoy as a result of our pioneer life."—*Albert Lea Standard,* May 11, 1900. Dr. Blackmer spoke of the Hon. Henry M. Rice who, in 1841, spent the summer here hunting elk, deer, and other game; of the first townsite operator at Albert Lea; of the territorial legislature and the organization of the counties; and particularly of the first county seat contest between Albert Lea and Bancroft. He said:

"Albert Lea won by a majority of 165 votes. This important decision was brought about by the free use of whisky and the free distribution of a few town lots. In a few places women and children voted, and all the immigrants who passed through Albert Lea and Pickerel Lake were induced to stop and vote.

"In 1857 there was a large immigration into Freeborn County, and that fall was the beginning of hard times that lasted until the Civil War created a demand for wheat. Our nearest railroad town was McGregor, Iowa, 140 miles away. Wheat was then worth sixty cents a bushel, and it took ten days to make the trip. Farmers would take a load of wheat and dressed pork to market at McGregor and haul back merchandise for the merchants. Often when weather and roads were bad, the farmers came back in debt, having used up the provisions for expenses. By the spring of 1858 starvation began to stare the people in the face. That year was appropriately called "1800 and Johnny Cake," except that there were dozens of families who had no Johnny Cake. Quite a few lived on leeks, milk, and wild artichokes. Game and fish were plentiful, but few people had money enough to buy shot and powder. Fish seines were drawn regularly below the dam, but there was no salt to prepare fish with. In the air holes in the lake, tons of fish were caught. The boys in Shellrock had no money to play penny-ante with, and so they chipped in with suckers and called with pickerel."

(To be continued in the October issue)

President's Letter

LET'S NOT "LET GEORGE DO IT"

In judging a man, we look not only at what he has—his skills, his wordly goods, the influence he wields—but also at what he is. We look for an intangible something within him—his personality, his soul. Because we cannot readily look into a man's soul and evaluate what we find there, we must rely upon his actions with regard to his family, his fellow citizens, his community, to serve as the index to his inner makeup.

The medical profession today is judged by the public in much the same way. Its individual members are appraised by the people who look to them for service and help, not only according to their proficiency at relieving suffering or diagnosing a pain in the stomach (although it must be said that that factor counts for much), but also for their cordiality, sense of humor, cooperativeness, participation in community life and countless other qualities. The entire profession is being viewed by its public as the sum total of all the doctors which the individual members of the public have met, done business with or heard about. Unfortunately, if a doctor among the lot repeatedly fails to meet with his patients' expectations, his failure tends to detract from the entire profession. This fact has been dwelt upon by many a speaker and writer before, but it is important and bears repeating.

When life in America was less urban, less complex, the family doctor held a remarkably strong position in his community. He participated actively in civic matters, and it can truly be said that his life was dedicated to the people whom he had chosen to serve. In turn, he was repaid by the love and respect of a grateful community. What he lacked in scientific knowledge, he made up in human understanding. The scope of medical science today utterly dwarfs the efforts of medical science a generation ago, but what of our stock of those intangibles that make up the *art* of medicine? Does our command of this art anywhere nearly equal the mastery possessed by our forebears?

An "M.D." is traditionally a symbol of intelligent leadership. Yet many who bear this title exert themselves only where medicine is concerned, to the neglect of civic responsibilities, social service activities and community interest. Admittedly, the practice of medicine is demanding upon time and energy. Likewise, physicians are continually performing services for which they receive inadequate return or no return at all. But these services do not excuse any of us from supporting and contributing to those causes which are sincerely promoted in the interest of the less fortunate. Giving voluntarily to the needy is a practice of a free society. Either we must continue this practice or change it for a system of compulsory taxation to support a government-supervised dole.

We cannot expect the public to support the cause of free medicine if we do not give back to our communities in a measure at least proportionate to what the community has contributed to our well-being. In so doing, we of the medical profession can add materially to our prestige and good will. But there is another, broader consideration which involves the fundamental precepts that underlie our American freedom: to help assure the continuance of our type of free society, the members of all professions are going to have to do something more than just exert their skill as competent technicians or artisans. Above and beyond the daily job, there must be time out for genuine good citizenship. None of us, sensing the civic responsibilities and opportunities which daily confront us in our respective communities, can afford to shrug our shoulders and say, in effect, "Let George do it." If we do, we are being dishonest with ourselves as professional men, because we comprise an all-too-limited segment of the American public which, by training and ability, is able to exert powerful influence for good on behalf of our communities and our country.

SOCIALIST BORERS

AMERICAN Medicine and the Political Scene, a Washington report published every week or two by Marjorie Shearon, Ph.D., furnishes a keen analysis of legislative activities, particularly those affecting medicine. Her leaflet of August 20 offers further evidence of the socialistic activities among government officials.

It may not be generally understood that the Federal Security Administration, headed by Oscar Ewing, is made up of the Social Security Administrations, the United States Public Health Service, the Office of Education and other miscellaneous units including the Bureau of Research and Statistics. This is a billion dollar concern, and the head of the Federal Security Administration is in a position to exert widespread influence in favor of socialism, if he is so inclined. There is evidence that he has done so.

To quote from the leaflet of August 20:

"The Bureau of Research and Statistics in the Social Security Administration is headed by Falk and Cohen, protected by Altmeyer, and officially approved by Ewing and Truman. There is now ample evidence in the published record and even more ample evidence not yet presented that this particular cell in the Government has for years exerted an influence out of all proportion to its size. Falk and his associates have produced an enormous amount of material designed to sell the Wagner-Murray-Dingell Bills, or something like it, to the people at large, to organized labor and social workers in particular, and to Congress first, last, and always. Altmeyer and Cohen, or their representatives, have preached the Gospel of Geneva, i.e., the Socialist program of the International Labor Organization, up and down this hemisphere and in the capitals of Europe and Asia. This whole campaign for national compulsory social security, including tax-supported medical care, has been paid for by the American taxpayer."

Here we have, then, an administrative department of our federal government, whose officials favor socialism, using tax-supported facilities to influence legislation, absolutely contrary to the Constitution.

What this element in our government has in mind in the way of socialization of our national economy is well illustrated by the Report of the Mission to Japan, in which a social security program for the Japanese is proposed whereby old age survival, invalidity, disability, and unemployment benefits, as well as medical care would be provided which would require as much as a 35.2 per cent payroll deduction. This plan would be the last word in a social security program and would provide little opportunity for a saving program. Add provisions for food, clothing, and shelter and you have a complete socialistic state.

It is high time that we had a house cleaning in Washington, and an elimination of those officials who have been using their influence to bring on a socialistic government. The social security program we have at present has doubtless come to stay. It involves enormous expense as it is, and certainly the addition of medical care would be a step toward complete socialization and eventual adoption of a socialistic state.

The people of the United States have not supported a socialistic political party, and it can be properly assumed they do not favor a socialistic state. It is not incumbent on government officials to use the power of office to change our national form of government.

ADULT HYGIENE AND GERIATRICS

THE INDIANA State Board of Health has developed an aggressive department under the direction of Dr. William F. King, and designated it Adult Hygiene and Geriatrics. Dr. King is chairman of the education committee of the American Geriatric Society. He urges his fellow committee members to develop interest and action in our respective states.

There is little need, presently, to quote for practicing physicians the rising tide of statistics that attest life extension and the preponderance of chronic disorders among our patients. Indiana reports that 50 per cent of current deaths are due to chronic diseases, in contrast to one hundred years ago, when 5 per cent were so listed. More than one-third of Indiana's population is now over for-

ty years of age, when chronic disorders date both to mortality and morbidity. Doctors are most happy, however, in the curing of acute or preventable disorders.

It is implied that medical students, due to the overcrowded curriculum in all schools, do not get enough indoctrination in terms of the problems of the aged which their future practice will provide and display. It is likely that the issues of aging, senescence, degeneration and malignancy are stressed unduly as *disease patterns* (pneumonia, coronary disease, diabetes) and the import of the social, economic, rehabilitation and adjustment factors in geriatric practice are considered on a par with cultural, political and international relations. The young practitioner soon finds out what it means to "become an umpire" instead of a healer for 40 to 60 per cent of his clientele. He gives them direction and guidance; he offers "cancer control" but his percentage of "cures" fades as chronicity obtrudes. Our medical journals of every type have the opportunity to step in where the medical schools leave off. Regional and national societies are encouraged to feature in their programs more papers and discussions dealing with Geriatrics and Gerontology. Two excellent journals now represent these two medical fields. They should be read much more widely.

E. L. Tuohy, M.D.

POLIOMYELITIS IN 1948

AUGUST, as a rule, is the month of greatest incidence of poliomyelitis. Why this variation in season and localities, we do not know.

The epidemic this year promises to be one of the worst, although that in Minnesota is comparatively mild. According to the U. S. Public Health Report of the week ending August 7, 1,239 new cases were reported for the nation at large, a slight increase over the preceding week. The incidence, however, showed a slight decrease in all three of the states where the epidemic has been the worst—in North Carolina from 212 to 179, in California from 224 to 177, and in Texas from 82 to 81. Through August 9, a total of 1,316 cases had been reported in North Carolina, for the most part in the western and central parts of the state.

The total number of cases reported in the nation up to August 7 was 7,039, as compared with 1,937 in 1947 and 5,450 in 1946, as of that date. In 1946, the year in which Minnesota was so hard hit, a total of 8,841 cases had been reported for the nation up to August 17, the final figure for the year being 25,698.

The Minnesota State Department of Health has kindly furnished the following figures for 1948: Minnesota up to and including August 25 has had reported 340 cases—61 from Minneapolis, 17 from Saint Paul, 1 from Duluth, and 261 from the remainder of the state. Freeborn County has reported 56 cases and Faribault County 71. Total deaths reported for the state had been 18.

In 1947, only 201 cases and 13 deaths were reported for the entire state. In 1946, however, cases numbered 2,881 with 226 deaths.

It is to be fervently hoped that the large amount of research now under way will discover a means of preventing the paralyzing action of this virus which is undoubtedly harbored by many carriers.

SOCIALIZED MEDICINE

IN May, Governor Dewey and former Governor Stassen visited Oregon preceding the primary election in that state. During that visit Governor Dewey was asked to address the House of Delegates of the Oregon State Medical Society, which he did as follows:*

"This is a subject . . . with which I have had a rare and unique experience. I had the idea a few years ago that the widespread movement to broaden the base of medical care could be met by government action if the doctors were put in charge. In fact, . . . I thought I would try it out in New York . . . I appointed a commission of nineteen people . . . They hired a research staff and then went to work.

"Finally after . . . eighteen months the research came through . . . I was thoroughly convinced, beyond a shadow of any possible doubt, **that compulsory medical care was unworkable, that it would bankrupt our society and destroy the standard of medical care in our nation, and it would be the greatest catastrophe in the United States.**

". . . I had felt all along that if there was any merit to this thing it . . . should be done on a state level and kept close to the people, and we ought not to use one hundred and forty-five million people as guinea pigs. We ought to use it on a small level and if it failed abandon it . . . We got the Saskatchewan program, the New Zealand program and the Australian program **and it was absolutely clear on the record that every time they tried to compel people to pay a certain sum to government for medical care they destroyed the medical care they were to receive.**

*Quoted from an editorial entitled "Dewey on Socialized Medicine," North Carolina Medical Journal, July, 1948, page 356.

"Compulsory, socialized medicine is no good. It cannot be done. Accordingly, I have spent the last two years knocking down every proposal that anybody has made to regiment the medical profession and the people of America through any program of socialized medicine. By making speeches publicly at every meeting of people that would listen to me on the subject, I have made clear that we have actually been through this thing, this thing which cost the people of my state $200,000 to find out about. I don't want the money wasted. I don't want to run the risk of happening to the health of our people what has happened to the health of every group of people which has tried **to drag the medical profession down to the Socialists' level. You won't drag anything up. You will enlarge the volume of medical care but utterly destroy the quality of medical care the minute you try that process."**

As a result of Dewey's unequivocal stand against compulsory medical care on a national basis, the physicians of Oregon put on a whirlwind campaign in his support. The Oregon physicians also sent letters to other physicians throughout the country urging Dewey's nomination in Philadelphia. The results in Oregon and Philadelphia are now well-known history. The physicians of Oregon apparently were impressed by Dewey's stand and felt uncertain of Stassen's attitude.

Governor Warren, on the other hand, is well known to have just as decided views favoring political medicine and has twice attempted to establish it on a state-wide basis in California. It is to be hoped that, if elected vice president, he will not be able to influence Dewey to change what seems to be his well-considered opinion.

President Truman, on the other hand, has been a strong proponent of the Murray-Wagner-Dingell Bill and has urged its enactment in Congress.

The physicians of Oregon have the feeling that Dewey's impromptu talk before the House of Delegates of the Oregon State Medical Society had much to do with his nomination. Certainly his stand appeals to the profession throughout the country.

INACCURACIES IN BIRTH CERTIFICATES

The need for filing accurate and complete birth certificates as early as possible after the birth of a child is being stressed at present by the Division of Vital Statistics of the Minnesota Department of Health. The division is encountering a great many problems due to inaccuracies in birth certificates and delays in filing.

"Doctors throughout the state are strongly urged to fill in birth certificates accurately and transmit them within five days after a baby's birth to the registrar of the city, village or township where the birth occurred," says Mr. J. W. Brower, acting director of the Division of Vital Statistics. It is essential, he points out, that birth certificates be legible, and that spellings of all names, and dates, be absolutely correct. A birth certificate that has been changed in any particular is not accepted by the courts as *prima facie* evidence, nor is a birth certificate that is filed as long as six months after the birth of the child concerned.

"Failure to file a birth certificate may result in a great deal of inconvenience and trouble for a person in later life, when it becomes necessary for him to present such evidence in order to establish proof of citizenship for employment, military service, a foreign passport, the right to vote or to hold elective office, or proof of age for obtaining life insurance or a pension," Mr. Brower states.

The process of securing delayed birth certificates is complicated, both for the individual concerned and for the Vital Statistics office, because it is often very difficult and sometimes impossible to obtain the evidence that is required by law for the filing of delayed certificates. It is much better if the birth certificate is properly filled in and filed shortly after the birth of the child.

Physicians are further urged to use a permanent type of ink in filling in birth and death certificates and other official documents. Records made with ballpoint pens have a tendency to fade and thus may become valueless.

Vaccination with BCG does not provide complete protection against tuberculosis and, until further controlled studies are conducted, cannot be recommended for the general population. However, since it appears to provide some degree of protection, its use is recommended for members of groups constantly exposed to tuberculosis if they have a negative reaction to the tuberculin test.—ATS Chemotherapy Comm., NTA, Nat. Tuberc. A. Bull., March, 1948.

NATIONAL HEALTH LEGISLATION

(Continued from Page 980)

very freedom and opportunity we are seeking to preserve and expand.

The progress achieved by the slower method of careful study of each problem and cautious and economical experiments preceding major programs may seem slow to those who want Utopia tomorrow, but so far in history all the promises of the leaders who insisted on trying to achieve Utopia in one jump have been redeemed only in the base coin of dictatorship and human slavery.

The United States will achieve far greater and more rapid progress in the field of public health, as in others, if we stick to the principles of freedom through which we have already achieved so much.

MEDICAL ECONOMICS

DOCTORS, PHARMACISTS HOLD MEETING AT DULUTH

At the invitation of the Duluth Associated Pharmacists this spring, Duluth physicians were invited to a dinner meeting designed to promote interprofessional good will. The event was a highly successful one and almost immediately desirable results were obtained stemming from the mutual understanding and friendly feelings that were given a substantial boost. There is promise that the compliment will be returned by the physicians. Thus a definite start has been made on the long-advocated program of improving interprofessional relations. This worthy beginning stands as an example to other communities.

An immediate development was an invitation by the St. Louis County Medical Society for the Duluth Associated Pharmacists to join with them in appointing committees to co-operate and exchange ideas on new and varied pharmaceuticals, especially those frequently duplicated.

It is felt by the Duluth professional people that both the doctors and the pharmacists can derive a great deal of benefit from co-operative effort; and through such effort there will develop a better understanding of mutual problems. Ultimately, better service to patients, customers and to the community will result.

Co-operation Long Advocated

For a long time, professional leaders have advocated closer ties between the various groups engaged in serving the public, not only to bolster their positions and their efforts to preserve freedom of enterprise, but to enable them to render better, more effective and more economical service to the people. Members of the health professions outside of medicine, for example, are an important "public" which medicine must include in any consideration of "public relations." In like manner, doctors are an important "public" which the pharmacist, the hospital administrator, the nurse, and the other professionals must consider. But such an enterprise as the Duluth meeting is more than just good public relations; it provides a means for the members of the professions to discover the interdependency of all groups which exists in a democratic society such as ours. It gives doctors a chance to see that pharmacists are concerned about professional relations and public relations just as is the medical profession, that they are as much in need of customer confidence as the doctors are in need of building up confidence on the part of their patients. Minor irritations and major problems can be cleared up co-operatively—everything from the unthinking dispatch by a busy physician of a prescription written unintelligibly to the addition of meaningless names to pharmaceuticals on the part of drug houses. Three definite steps have been advocated for the pharmacists and physicians to take in the interprofessional program begun at Duluth:

1. Physicians should strive to become thoroughly acquainted with the proven value of drugs prescribed; they should keep themselves informed.
2. Pharmacists should make known their problems when they involve the medical profession so that the profession can co-operate in remedying the difficulties.
3. Physicians and druggists should present their problems to drug manufacturers and obtain their co-operation.

With the understanding coming from a definite program such as the one now under way, physicians and pharmacists can join hands for the best possible service to the public.

STEPS TAKEN TO TACKLE MENTAL HEALTH PROBLEM

Under way at present in Minnesota is a definite drive to "do something" about the conditions in this state with regard to the care of the mentally ill. It has been long realized that the treatment for mental patients is more or less inadequate all over the nation, and with the passage of the Mental Health Act by Congress funds will be available to correct the undesirable conditions that exist.

Prior to this time, because of the lack of funds and facilities, it has been impossible to provide salaries attractive to qualified personnel and to render something more than just custodial care for mental patients. Now with the backing not only of a federal appropriation for improvement of services and for public health education, but also of the Governor and a number of influential citizens, it seems that remedial measures will eventually be instituted.

Minnesota's program begins with an annual grant of $59,623 from the federal government under the Mental Health Act. These funds will be administered by the recently created Mental Hygiene Unit of the State Health Department and will finance a statewide program of service and education. In addition, there is strong indication that a program for improved facilities and treatment in Minnesota institutions will be laid before the state legislature in 1949.

The press in this state has carried on a most vigorous campaign to expose the conditions prevailing in Minnesota's institutions. Nevertheless there is some controversy over the exact status of these "conditions." The Governor's committee of citizens appointed to review the treatment of mentally ill in this state reports one set of facts and figures, while the Legislative Research Committee has made a report taking issue with the previous findings. No one disagrees, however, on the major point involved—that Minnesota's mental patients should and can be getting better treatment and care.

Another Study Under Way

Most recently announced is a study to be made by the State Division of Public Institutions to determine what the institutions need in the way of additional personnel, housing facilities and food preparation, the findings to be presented to the 1949 Legislature, which will then be asked to appropriate sufficient funds to meet the needs.

Governor Youngdahl has promised that improvement in mental health will be a Number One project when the Legislature convenes. He has asked specifically for the following:

1. More adequate staffs for the state's seven institutions, with a near doubling of present personnel and with salary scales attractive to workers, doctors and nurses equipped to provide high grade care.
2. A training program for personnel, including a psychiatric training institute.
3. Better food for patients and better clothing and therapy equipment.
4. Appropriations to cover increased building costs since the original construction program was laid out.
5. Mental Health Clinics in local communities.

There is also talk of recommending that a new institution be erected, probably at Alexandria to take the burden off the other institutions in the state. An addition of 150 beds for senile patients at Moose Lake state hospital was recently authorized and the contract has already been awarded.

ANTIVIVISECTION CITED AS THREAT TO MEDICINE, LIFE

Although it used to be a harmless cult, the antivivisection movement has become a menace to medicine and to human life. So states a recent article in the *Saturday Evening Post* (July 24). With facts and figures to back up this contention, the author, Dr. Virgil H. Moon (professor emeritus of pathology, Jefferson Medical college) and his collaborator, David G. Wittels, show how what used to be a harmless belief held by some that it is morally wrong to experiment on living animals has been turned by clever opportunists into a racket.

The antivivisectionists are not to be confused with the true humanitarians who seek to protect animals from mistreatment and cruelty. The antivivisectionist puts animals above humans—at least, the only alternative to performing experiments on animals which the antivivisectionists offer is that of making human guinea pigs out of charity patients! This cult actually went so far, according

to Dr. Moon, as to send congratulations to Adolph Hitler when he outlawed animal experimentation in Germany in 1933. It is common knowledge now how the Nazis carried out their cruel and vicious tests on living persons.

Without experimenting on animals to determine the effects of drugs or to observe the behavior of living tissue in the presence of cancer, leukemia and other maladies, medical research must needs come to a halt. Hence, as the title of the *Post* article points out, these cultists are "Trifling with Your Life!" Such discoveries as penicillin, sulfas and streptomycin had to be tried first on animals before they could be administered to human sufferers from pneumonia and tuberculosis. Countless lives have been saved by drugs perfected with the aid of our animal friends, with this research being conducted by responsible persons who keep the distress of the animal to the minimum. But the antivivisectionists maintain it is morally wrong to save the life of a dying person and interfere with divine authority which had marked him for death.

Seek to Disparage Medicine

The antivivisectionists seek in other ways and by other false teachings to disparage the work of medical science.

They claim, for example, that the germ theory of disease is false; that cancer, tuberculosis and heart fund drives are carried on simply to collect money for animal experimentation; that parents should forbid vaccination or inoculation of children because materials used are merely frauds; that government reports on the fight against disease are written by physicians who are merely trying to build up their prestige; that rabies is not transmitted by dogs and the contention that dogs are responsible is a deliberate attempt by health departments to "scare" the people. Antivivisectionists also claim carrot juice is effective against cancer and that vaccination causes syphilis. Such teachings, up to now, the medical profession thought to be such utter nonsense that it could safely be ignored, merely laughed off or stifled by pointing out the facts about the lives saved through products discovered and tested through animal experimentation.

Not so, however. These "crackpots" have sold their ideas to politicians and to professional promoters. Their twisted beliefs are percolating into legislative halls and are being passed along to people in public life who are respected or idolized by millions—for example, motion picture actors and newspaper publishers. Funds with which to propagandize and high-pressure the public into swallowing their false doctrines continue to pour in.

Medicine Must Act

The need for medicine to counteract this movement is obvious. It is hoped that the article on antivivisection will be read by a large number of doctors and other thinking persons for the facts speak for themselves. Legislators should be warned to be on guard against these false doctrines, for the health of the people is at stake.

It can be pointed out that the appeal of the antivivisectionists is irrational. It can be shown that although this group forbids inoculating rabbits with polio virus, for example, it does nothing to decry the trapping of mink to make expensive fur coats.

Nor does the antivivisectionist look with disapproval on the clipping of a dog's tail, the branding of cattle or the spaying of a female puppy. These are classified as "operations deemed necessary by the animal owner" and are considered proper. No one should deny the existence of sincere sympathy for animals suffering needlessly; what must be combated is the commercializing of this sympathy into a vicious and unfounded attack on the humanitarian principles of curative and preventive medicine.

VETERANS ADMINISTRATION TRAINS OWN PHYSICIANS

A program for training medical graduates in Veterans Administration Hospitals throughout the nation, authorized by the Eightieth Congress, seems likely to be carried through in Minnesota.

The VA's current residency-training program, carried on in co-operation with the University of Minnesota, has been highly successful and has generally improved the quality of care rendered to hospitalized veterans in Minnesota.

Present plans are to expand this program and offer "two or more" internships to medical graduates from the University of Minnesota and also to some graduates from other schools.

It is planned to begin the first internships about June or July of next year. The interns will get one-year tours of duty and will be paid a maximum of $1,800 a year.

Minneapolis Surgical Society

Meeting of April 1, 1948

Dr. L. Haynes Fowler, Presiding

CARCINOMA OF THE BREAST

An Analysis of 100 Questionnaires Sent to Patients Operated Upon at Fairview Hospital

L. A. STELTER, M.D.
Minneapolis, Minnesota

Although interest in carcinoma of the breast has been dominant for fifty years, there never has been a period of more controversy concerning the diagnosis and treatment than the present decade. Medical libraries are full of literature on tumors of the breast, and whole books have been written with as many as eight and ten chapters devoted to cancer alone.

During the past year 175,000 persons lost their lives from cancer, and approximately one-tenth of these deaths were from breast cancers. There are five times as many radical operations performed for cancer of the breast as for tumors of the entire gastrointestinal tract despite the fact that gastrointestinal cancers are three times as common.

Pack and Livingston state that the reason for this unusual attention to breast tumors is the accessibility of the mammary glands and their functional, sexual, esthetic, and psychological significance. Yet we, as a profession, are still failing to reduce the annual death rate from cancer of the breast.

With the passage of the National Cancer Institute Act in 1937 and the increased lay interest through donations and contributions, this country has established a basis for more comprehensive work on the problem of cancer, its detection and prevention.

Since the etiology of cancer is such a widely disputed and unsettled question, this paper, for want of time, will not discuss these theories.

Pathological classifications of breast cancer frequently employed are as follows:

1. *Steinthal classification.*—A clinical estimation of the stage or extent of the disease at the time of treatment—a classification as to stage.

2. *The pathological classification* as to the stage of cancer.—Determination of the extent of metastatic spread by microscopic examination of the excised axillary nodes.

3. *Broder's classification.*—A study of the anaplasia or degree of malignancy of the cells which constitute the tumor—a classification as to grade, namely, Grades I, II, III, and IV, which represent an ascending scale of anaplasia of the component cells of the tumor. Grade I and Grade II signify cancer composed in a large part of adult and well-differentiated cells. These tumors are slow growing and less invasive. They are relatively radioresistant. Approximately 85 per cent of breast cancers fall within Broder's Grade III and Grade IV classification. These, theoretically at least, should prove radiosensitive.

4. *The clinico-pathological classification.*—(1) scirrhous carcinoma, (2) inflammatory carcinoma, (3) anaplastic carcinoma, (4) cystadenocarcinoma, (5) bulky carcinoma, (6) gelatinous carcinoma, (7) sweat gland cancer, (8) acinar cancer.

5. *The Lee clinical index of malignancy.*—A method for estimating the prognosis in individual cases, taking into account the above factors and additional clinical features noted.

The percentage of malignancies of the breast is closely related to the full maturity of the gland; and the age incidence, based on hospital records, is from forty to forty-nine years. Taylor has estimated that 73.5 per cent of mammary cancers occur in women past the age of forty years. There are many diagnostic signs of breast cancers, of which pain, nipple discharge, lump, retraction of the nipple, puckering of the skin, and palpable lymph glands are outstanding. Pain usually indicates a benign lesion, and a bloody or serous fluid discharge is only suggestive. Any single lump in a woman's breast during the age incidence of cancer should be considered cancerous until proven otherwise. Punch biopsies and x-ray photography are impractical. The only accurate means of diagnosis is excision and biopsy. We must teach our colleagues to be radical, with early excision of solitary lumps and examination by the microscope.

Our largest problem in cancer prevention is lay education. Perhaps such lay information as that printed in the *Readers Digest* of August, 1947, may stimulate women to submit to early examination.

The work of Dr. Augusta Webster, director of the Cancer Detection Clinic at Women and Children's Hospital, Chicago, and that of Dr. Leonard B. Goldman at the Queens General Hospital, New York, exemplify the progress in cancer detection work.

Recently more than 500 physicians gathered at Louisville, Kentucky, for a unique symposium on cancer problems and for the dedication of the world's first x-ray mobile unit for cancer detection. Keynote of the symposium was: "the best cancer clinic in the world should be in the office of the private physician." It is up to him to detect cancer early and help eliminate the disease (Table I).

According to Harrington, factors which influence results of surgical treatment are (1) the extent of the malignant involvement at the time of operation, (2) the thoroughness with which the operation is performed,

TABLE I. TREATMENT RESULTS

Taken from Dr. Frank E. Adair's reports, *Annals of Surgery,* (Jan.-June) 1932

Treatment	Number	Died of Other Disease	Basis of Calculations	Number Living	Per Cent Living	Died of Cancer	Per Cent Died of Cancer	Living With Disease	Per Cent	Living Without Disease	Per Cent
Surgery alone	23	3	20	2	10	18	90	0	0	2	10
Irradiation alone	37	4	34	12	36.3	21	63.3	4	12.1	8	24.2
Combined Surgery and Irradiation	137	9	128	52	40.8	85	66.4	3	2.3	49	38.2

TABLE II. SURVIVAL RATES FOR DIFFERENT PERIODS AFTER OPERATION

Taken from Dr. S. W. Harrington's statistics reported in the *Pennsylvania Medical Journal,* (Jan.) 1940

	3 Years		5 Years		10 Years		15 Years		20 Years	
Axillary Metastases	Patients Traced	Per Cent Survival	Patients Traced	Per Cent Survival	Patients Traced	Per Cent Survival	Patients Traced	Per Cent Survival	Patients Traced	Per Cent Survival
Present	2987	42.0	2743	28.1	2110	15.5	1385	10.3	726	6.6
Absent	1729	83.1	1522	73.1	1109	54.5	752	41.9	410	34.9
Total	4716	57.1	4265	44.2	3219	28.9	2137	21.4	1136	16.8

(3) the degree of malignancy as shown by microscopic examination of the primary lesion, (4) the prevalence of other associated conditions such as pregnancy, (5) the general constitutional diseases, and (6) the age of the patient.

About 40 per cent of the breast cancers at the Mayo Clinic did not have metastases in the axilla at the time of operation. The proportion of this group living three years or more after operation was 85 per cent, or almost twice as many as in the group with axillary metastases, where the percentage living was 45.3. In the five, ten, fifteen, and twenty-year survival ratios of patients without axillary metastases, it was found that the improvement increased progressively over the group with metastases (Table II). The prognosis, then, is directly proportional to the size of the primary tumor, the metastases, and the grade of malignancy.

The operability of the patient must be determined first before operation is performed. If axillary involvement is present, x-rays of the lungs and the spine must be taken. The operative procedure is important. Since the introduction of radical surgery by Halsted, the method most widely accepted by the profession, the incidence of cure has been greatly increased. It is based on the theory that cancer spreads through the lymph stream; and the greater the extent of dissection, the better chance there is for cure. If these concepts are true, the most important considerations in treatment are early recognition and immediate, complete removal of the diseased tissues. If the condition is confined to the breast alone, a complete eradication of the disease can be expected.

Dr. McNealy, speaking before the Alumni Association of the Cook County Hospital interns and residents in November, 1947, stated that "a breast with a single solitary lump one centimeter in diameter removed by simple mastectomy would cure the patient." Tumors that have axillary metastases are too far advanced to cure as they already have spread beyond the accessable tissue for excision. He condemned excision of solitary lumps and then closing the wound and waiting for microscopic examination. A planned attack is therefore essential: hospitalize the patient, be prepared to do a mastectomy—simple or radical—excise the lump, and have it examined immediately. One should never remove a lump without having a competent pathologist at hand.

With modern preoperative and postoperative care and the use of intravenous fluids, glucose, normal saline, plasma, and blood, haste is not essential in performing this important operation. Haagensen, in the symposium on cancer of the breast, January, 1946, gives a masterful description of the radical mastectomy. He emphasizes that the procedure takes five hours or more and warns that the operator must be prepared to prevent shock. He evaluates the principles of both Halsted and Willy Meyer, namely:

1. The excision of the skin over the whole breast, covering the defect with graft.
2. Excision of both pectoral muscles.
3. Complete axillary dissection.
4. Removal of excised tissue in one block.

The aim of postoperative irradiation is twofold: (1) to attempt destruction of cancer cells left by incomplete operations, and (2) to control recurrences. From the statistics shown in Table III, it is evident that there is little encouragement from its use except for the salving of our conscience and the moral responsibility to our patients to use all possible measures to obtain a cure.

Until newer techniques and procedures pass the test of reducing the mortality, we should use the combined tools of radical mastectomy and postoperative irradiation.

One hundred questionnaires were sent from the record department of Fairview Hospital to patients operated upon for carcinoma of the breast during the period from

TABLE III. SURVIVAL RATES FOR DIFFERENT YEARS FOLLOWING RADICAL AMPUTATION AND IRRADIATION
Taken from Dr. S. W. Harrington's statistics

	3 Years		5 Years		10 Years		15 Years		20 Years	
	Patients Traced	Per Cent Survival	Patients Traced	Per Cent Survival	Patients Traced	Per Cent Survival	Patients Traced	Per Cent Survival	Patients Traced	Per Cent Survival
Group with axillary metastases:										
With irradiation	2240	43.2	2011	29.4	1457	16.1	821	9.9	228	6.1
Without irradiation	747	38.6	732	24.3	653	14.1	564	10.8	499	6.8
Group without axillary metastases:										
With irradiation	1014	84.4	858	75.4	588	55.1	354	40.1	100	36.0
Without irradiation	715	81.1	664	70.2	521	53.7	398	43.5	310	34.0

1935 to 1946 inclusive. The purpose of this work was to stimulate interest among the members of the staff in follow-up work and to determine what our records might reveal on carcinoma of the breast.

No attempt was made to grade the cases, as illness in our pathology department necessitated the work of several different pathologists. However, the cases were all diagnosed as cancer in the clinicopathological classification—scirrhous carcinoma, adenocarcinoma, medullary carcinoma, et cetera.

The questionnaire sent to the patients was similar to that used at St. Mary's Hospital, Duluth, and was as follows:

Case No.....

was a patient in Fairview Hospital in .....

The final results of this case are a matter of great interest to the Medical Profession and this Hospital in order to classify its records. Will you kindly answer the following questions and mail your reply in the enclosed stamped envelope?

Have you been in good health since leaving the hospital?

What is your present condition of health?

Have you had any treatment since leaving the hospital? If so, what has been the nature of this treatment?

When did you last see a physician?

Name of physician last seen:

Remarks:

A period of three months was allowed for the return answers, at which time we had sixty-six answers. Of the sixty-six patients, thirty-seven were living and well, and twenty-nine had died. These cases cover the work of eleven different operators. It was noted in analyzing the cases that in those cases in which radical procedures were performed followed by irradiation therapy, the results were more encouraging.

The percentage living, as determined by these questionnaires (Table IV), is not the percentage of cures for the period given in comparison to the number of patients operated upon, but it is a percentage of those who answered the questionnaire.

TABLE IV. A REPORT OF 100 QUESTIONNAIRES SENT TO PATIENTS OPERATED AT FAIRVIEW HOSPITAL

Year	Period	Number of Answers	Number Living	Number Dead	Percentage Living
1935	12 year	4	3	1	75%
1936	11 year	2	2	0	100%
1937	10 year	1	0	1	0%
1938	9 year	3	1	2	33%
1939	8 year	2	1	1	50%
1940	7 year	2	1	1	50%
1941	6 year	15	4	11	26%
1942	5 year	3	2	1	67%
1943	4 year	9	4	5	44%
1944	3 year	12	8	4	67%
1945	2 year	11	9	2	82%
1946	1 year	2	2	0	100%

Discussion

Dr. N. K. Jensen: When I took my board examinations, I was examined by two nationally prominent surgeons in the oral part of the examination. Their first question was, "What would you do for a carcinoma of the breast?" I replied that I would do a radical mastectomy with axillary dissection. The next question was, would I follow up with x-ray irradiation? I was in the room another half hour without answering the second question because the two examiners got into an argument about whether or not to use irradiation.

It has never been adequately demonstrated by any statistically sound figures that postoperative irradiation is worth the physical trauma of the irradiation, the postroentgen illness and the resultant increased fibrosis. I am wondering if I am misreading the statistics, and I should like to know what others of this society believe.

Dr. Horace Scott: I should like to second Dr. Jensen's remarks. I have been wondering about the value of x-ray therapy. I should also like to raise a question to Dr. Stelter about another form of therapy which he did not mention, that of castration of a young woman before menopause. Might it be of value in the treatment of these individuals below forty-five years of age?

Dr. Robert Tenner: Dr. Stelter's paper represents a good deal of worthwhile work and study, and certainly is a good project for many of our other hospital staffs to follow. I wonder about the advisability of excising so much skin, thereby necessitating skin grafting, as mentioned in the paper. In most clinics and hospitals this is not the usual procedure. I have been under the impression that the recurrences in the scar which are sometimes seen do not represent islands of tumor which have been left in the skin but rather recurrence from the underlying structures or implants spread around at the time of operation. I would like Dr. Stelter to enlighten us on this question.

Dr. S. Maxeiner: I think that in the treatment of cancer one must not lose track of the fact that we have two problems: one is curative and the other is palliative. Some may say that it is not worth while to remove a

carcinoma of the breast, but who wants to live with one? I have made it a rule to take them off, almost regardless of what they look like. I operated upon a patient with a cancer as big as the palm of my hand and large axillary lymph nodes, and she lived five years, during which time her six daughters grew into young womanhood. It certainly was worth while. It was not curative but palliative. If one can provide the patient with six to twelve months of freedom from an odorous, sloughing mass, it certainly is worth while. One recent patient, who was unable to live in the home with her own child because of the stench, was completely relieved and able to be with her family to the time of her death.

Finsterer of Germany says that if the primary lesion is resectable, he must remove that lesion in spite of metastases elsewhere. Life is more comfortable without it than with it. We had one man who had had a carcinoma of the stomach removed, who was collecting insurance. They stopped his insurance because he was feeling so well. However, metastases to the liver finally got him.

We use x-ray routinely on patients with metastases. We have seen metastases in the skin and cervical nodes, which you could feel with your finger, grow while they were getting x-ray treatment, but I do think that some of them are responsive to treatment.

Someone asked about sterilization. We have tried it in several instances but have seen no demonstrable benefit. These, however, have been in patients with fulminating carcinoma. We are extremely radical with skin removal, and I suppose that 70 to 75 per cent are grafted at the time of the removal of the breast.

Dr. Albert Cottam: I have a very distinct recollection of an article by Dean Lewis published in the *Annals of Surgery* in which he analyzed the patients who had been operated upon for breast cancer without skin removal. Fifty-one had showed recurrences in the skin. I have a personal case which happens to concern my own sister, eighty years old, living in Cape Town, South Africa, who noted a lump in her breast. Unfortunately, she wrote to a newspaper doctor who replied that it was probably benign. It continued to grow, and she put herself in the hands of a group of doctors who performed a radical excision followed by x-ray. She wanted me to write to her doctors and find out what was done. I wrote them asking that she be told the truth. It sounded like a malignancy to me, and the fact that they were using x-ray therapy seemed to me that they must have found a malignancy. Her husband was Dr. George Heberden, the fifth doctor in line from the doctor who made notable contributions about the time of the American Revolution. You have heard of Heberden's nodes. He also did pioneer writing on arthritis deformans and angina pectoris.

Dr. Herbert Peterson: The question in my mind always has been whether or not the treatment of breast carcinoma is ever curative, rather than just palliative. The fact that we refer to one-year or twenty-year cures is evidence that there is doubt in our minds as to actually curing a patient with either surgical or roentgenological therapy, or both. It has always been my opinion that we should give the patient every consideration, every "break," and that in no way should any form of treatment be omitted if we can prolong life with some degree of comfort.

Dr. L. H. Fowler: This discussion brings to mind two patients, neither of whom had any x-ray therapy. One patient, a lady now over seventy years of age, is in the hospital at the present time with cardiac decompensation and hypochromic anemia. Dr. W. A. Hanson and I performed a radical mastectomy upon her for a large carcinoma (4 by 4 inches) with skin attachment, eighteen years ago. No evidence of recurrence can be found except periodic bouts of anemia. The second case is that of a woman upon whom I assisted Dr. E. Starr Judd perform a radical mastectomy in 1921 or 1922 for a large adenocarcinoma of the breast with axillary metastases. After nineteen years of good health, she developed a malignant lesion of the ribs and spine and subsequently died therefrom. The interesting question here is whether this patient developed a metastatic recurrence of the original cancer nineteen years later, or were these lesions metastases from a new growth? No local recurrence was present in the breast area. No other primary lesion could be found. Unfortunately no autopsy was obtained.

Dr. Stelter: In answer to Dr. Jensen's question regarding x-ray therapy, I should like to say that Broder's Grades 1 and 2a re x-ray resistant, Grades 3 and 4 are radiosensitive. When you take a group of cases, it does not seem to do a great deal of good. I think we should give the patient all the treatment we can. In answer to Dr. Scott's question of castration of these younger women, I have not enough information or experience on this procedure. I have read about using testosterone on cancer of the breast with metastasis. The article reports two cases of malignancy of the breast in which testosterone gave relief when there was bone involvement. The article appeared in the *Medical Clinics of North America*, January, 1948.

As far as the skin excision is concerned, I have not been as radical in removing the skin over the breast and grafting later. I heartily agree with Dr. Maxeiner that the more radical we are, the better chance the patient has. What woman cares to live if she has an ulcerating breast? Take it off, and everyone is happier.

I just want to emphasize one thing more: early excision and biopsy of the lump. Too many practitioners see small tumors and suggest coming back next month, by which time it may be a far-advanced cancer.

A RARE COMPLICATION OF INTESTINAL INTUBATION

OSWALD S. WYATT, M.D., and TAGUE C. CHISHOLM, M.D.

Minneapolis, Minnesota

Since 1938 the technique of intestinal intubation for decompressing by suction distended loops of small and/or large intestine has been developed and has gained wide acceptance. The unwieldy double-lumen Johnson tube was quickly replaced by the Miller-Abbott tube; more recently this is being replaced by the Harris, the Cantor, and the Honor tubes. Actually all of these more complicated tubes are merely refinements over Levin's simple naso-duodenal catheter and, as such, require precise care to achieve maximum effectiveness and to avoid serious complications.

Although the advantages of the nonoperative management of intestinal distention are beyond question, intestinal intubation, used injudiciously, can lead to serious and even fatal complications. It is not the role of this communication to discuss indications for the use of the Miller-Abbott tube, the technique of intubation, or the management of the intubated patient, but rather to recall some of the more common complications which have attended the use of the Miller-Abbott tube, particularly in children; to describe the case of a nine-year-old boy

in whom a rare complication of intestinal intubation was encountered; and to discuss, briefly, the merits of the Honor tube as an aid in avoiding such a serious complication.

Complications

In the nasopharynx, all who have used the tube are familiar with the "plugged nose" secondary to edema of the turbinates. This is particularly likely to occur in children, in whom the nasal airway is so nearly equal to the outside diameter of the tube. Minor epistaxis and pharyngitis, secondary to mechanical excoriation of the nasopharyngeal mucosa by the tube, are not uncommon. The most serious complications in the nasopharynx, secondary to employing the tube, include an occasional sinusitis, eustachian salpingitis and acute otitis media. These last two complications are especially prevalent in children, in whom the local developmental anatomy leaves the Eustachian tube mechanically receptive to retrograde secretions with ensuing infections.

In the larynx, Kaufman et al[6] have experienced such a degree of acute edema that tracheotomy had to be resorted to. Iglauer and Molt[5] have reported necrosis and permanent damage to the larynx as sequellae of prolonged intubation with laryngeal edema. Wangensteen[10] has commented upon damage to the arytenoid cartilages following prolonged intubation.

In the esophagus, the mucosa is well known for its thinness and friability; this is even more true in infants and children than in adults. It is extremely common to find severe erosion of the esophagus in the pediatric age group in whom intestinal intubation has been pursued over even a brief period of time. Vinson[8] has reported late esophageal stricture formation secondary to prolonged indwelling of the intestinal tube.

In the stomach, the problems of intestinal intubation in children are the same as those in adults. The difficulty of getting the tube past the pylorus and the great inclination of the tube to coil in the stomach are familiar problems. Occasionally knots have become tied in the tubing as it coils in the stomach or as it improperly prolapses into the duodenum. Mahon[7] has reported erosion of gastric mucosa with perforation and peritonitis secondary to intestinal intubation.

In the small intestine, secretions do accumulate in the loops proximal to the sucking tip, as is well illustrated in the case reported here in detail. Berger and Achs[2] have had the metal tip of the Miller-Abbott tube become fixed at the level of an extrinsic fibrous adhesion; subsequently the tip of the tube perforated the small intestine and peritonitis ensued. In 1940 Walker[9] reported on an experience in which the Miller-Abbott tube was advanced to the level of a small bowel obstruction to facilitate x-ray diagnosis; the barium inadvertently was introduced into the balloon which, fortunately, ruptured as it was withdrawn through the cardia of the stomach. It is an extremely common experience for those who employ the Miller-Abbott tube to any extent to have the lumen become occluded with intestinal contents. While still using a double lumen tube, Harris[3] reported an instance of intussusception accompanying an overdistended balloon. Several surgeons have encountered retrograde intussusceptions from the too rapid withdrawal of the Miller-Abbott tube, both with the balloon inflated and deflated.

The mechanical problems to which Miller-Abbott tubes are prone are common property to their use in all age groups. Leaking tubing, unusually flexible old tubing, leaking or ruptured balloons, leaking or transposed adapters—these complications are inherent in this kind of precision equipment.

Case Report

The following case report is presented to illustrate another type of complication resulting from intestinal intubation with the Miller-Abbott tube:

W. A., a nine-year-old white boy, was admitted on March 30, 1947, to the hospital service of Drs. Richdorf and Gibbs because of an eleven-day illness characterized by cough and abdominal pain. For the first two days of his sickness he had frequent chills, a coffee-colored sputum and a continuous high fever; his abdominal pain was generalized and not too prominent. For the four days just prior to entry he had had increasingly sévere abdominal pain with continuous vomiting. There had been a few loose stools on the two days before hospitalization.

Physical examination on admission revealed a temperature of 101.6° F., a pulse of 156 and respiration of 40 per minute. The blood pressure was 122 systolic and 80 diastolic in millimeters of mercury. The boy was extremely toxic and markedly dehydrated. There were râles over only the right upper and middle chest. The abdomen was distended, rigid, tender and with some intestinal patterning. Auscultation disclosed high-pitched, frequent borborygmi. Rectal examination revealed a tender mass 10 centimeters in diameter, filling the right pelvis and extending across the midline.

A roentgenogram of the chest on entry showed an increased density over the right upper and middle lobes. Abdominal films showed marked small bowel distention with fluid levels and no gas in the large bowel (Fig. 1).

The white blood count was 13,350, 80 per cent being polymorphonuclear leukocytes, most of which were toxic forms. The red blood cell count was 3,800,000, and hemoglobin 79 per cent. The urine specific gravity was 1.031, showed acetone and the sediment was normal.

For the first nine hours in the hospital, efforts were directed towards combatting (1) dehydration and acidosis with intravenous fluids, (2) right upper and middle lobe pneumonia with penicillin and later sulfadiazene, (3) peritonitis and small bowel obstruction with penicillin and streptomycin, high concentration oxygen and nasoduodenal suction. In spite of these efforts, abdominal distention clinically and dilatation of loops of small intestine radiologically were progressive (Fig. 2). Operation was decided upon.

Under pentothal and curare anesthesia supplemented with nitrous oxide and oxygen, the adbdomen was opened through a right rectus incision. Many loops of small bowel, averaging 6 centimeters in diameter, prolapsed into the field. A ruptured appendix with the tip blown off, and with copious amounts of foul-smelling creamy pus, was disclosed in the right gutter and pelvis. The remains of the appendix were removed. Many loops of darkish, moderately compromised small bowel were freed from their dense fibrinous adhesions about the mass in the pelvis. Collapsed loops of distal bowel immediately enlarged. A Miller-Abbott tube which had been placed in the stomach just before operation was milked manually through the duodenum into the upper jejunum. The closure was accomplished after the viability of all loops of bowel had been established.

Fig. 1. X-ray of chest and abdomen taken on entry to hospital, showing increased density over the right upper lung field and marked small bowel distention with fluid levels.

Fig. 2. Repeat x-ray of abdomen taken nine hours after entry to hospital, showing progressive dilatation of small bowel.

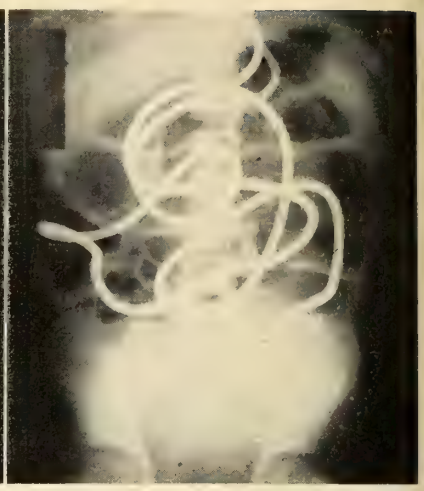

Fig. 3. X-ray of abdomen taken eighteen days after the initial operation, showing recurrent dilated loops of small bowel in spite of the adequate positioning of the Miller-Abbott tube.

Fig. 4. Photograph of distended Miller-Abbott balloon, 12.4 cm. in diameter, full of coagulated Varco's solution as firm as cement.

Postoperatively this boy's temperature rose to 104.2° F his pulse ranged from 110 to 150, and respirations were from 34 to 48 per minute. Penicillin, streptomycin, sulfadiazene, Miller-Abbott tube with Wangensteen suction, parenteral feedings and high concentration oxygen resulted in a definite improvement by the third postoperative day. By this time the Miller-Abbott tube had been satisfactorily advanced to the six-foot mark and its position was checked by x-ray. Although some flatus was passed by rectum and fluids were being taken by mouth, the abdominal distention persisted and the abdomen remained extremely quiet. By the fourth postoperative day the Miller-Abbott tube could be clamped off for two hours, but "gas pains" were too severe to justify the removal of the tube. At this time Varco's highly nutritious fluid was started orally, 30 c.c. every three hours. By the seventh postoperative day the boy was taking 75 c.c. of Varco's solution every three hours and was maintaining his proteins largely by the oral route. On this day he had his first soft bowel movement. Nevertheless, when his tube was clamped off for more than two hours, the patient had such severe pains he would scream to have the tube reattached to suction.

On his twelfth postoperative day, ten days after the administration of pooled plasma and three days after the discontinuance of sulfadiazene therapy, the boy became icteric. His temperature went up from normal to 101.6° F., and his pulse rose from 80 to 130. The abdomen was still distended. Bowel sounds were normal in pitch and frequency. The liver edge was down three finger breadths and was tender. The Miller-Abbott tube was still at the six-foot mark and irrigated well. An x-ray of the abdomen outlined a mass in the left lower abdomen and pelvis where the patient had maximal tenderness. By fluoroscopy both diaphragms moved freely on deep respiration.

The next day his jaundice had increased. A rough, systolic heart murmur, not heard before, became audible at the apex. On this day the tube irrigated less well than previously, although the balloon could be deflated and inflated with ease. By the sixteenth postoperative day his recurrent distention was severe. Upon repeated x-ray study there was again considerable gaseous distention of multiple loops of small bowel. Nasoduodenal suction was put down in addition to the Miller-Abbott tube, and high concentration oxygen therapy was reinstituted. The following day the small bowel was fairly markedly deflated and the stomach was emptied with the second tube positioned in the duodenum. The jaundice had begun to lessen. The rough heart murmur persisted. The pulse, nevertheless, was rapid, and the boy appeared desperately ill.

By the eighteenth postoperative day his distention had recurred. X-rays showed again increased dilatation of the loops of small bowel (Fig. 3). The larger lumen of the Miller-Abbott tube mechanically was sucking out well, but the balloon could not be inflated or deflated. Upon noting this an effort was made to withdraw the Miller-Abbott tube. This occasioned great pain in the left lower quadrant, and the tube could not be withdrawn. A second operation was immediately carried out.

Through a left rectus incision the abdomen was opened. Nearly all loops of small and large bowel were matted together with fibrinous and fibrous adhesions. The Miller-Abbott tube had failed to decompress the dilated loops of small bowel through which it passed. In the process of freeing the adhesions obstructing loops of small intestine at the brim of the pelvis, a gangrenous loop of

terminal ileum was broken open and a large Miller-Abbott balloon, nearly 13 cm. in diameter, full of coagulaten Varco's solution as firm as cement, was delivered into the field (Fig. 4). The tube, together with its balloon, was amputated *in situ*. The nonviable segment of ileum was resected and an end-to-end anastomosis was performed.

Postoperatively the boy developed a hypertension of 175 over 130. His temperature ranged from 101 to 102.5° F. His pulse remained about 150. Twenty-four hours after his second operation he began to expel flatus satisfactorily. His newly inserted Miller-Abbott tube worked nicely. Thirty-six hours after the operation his jaundice became intense. Four short-lasting right-sided convulsions followed. Forty-eight hours after operation his seizures became more frequent, longer lasting and more severe. Unconsciousness followed, and he died on his third postoperative day.

Discussion

It is not within our province to say that this boy would have recovered had he not had the development of this rare and unfortunate complication dependent on the administrative care of his Miller-Abbott tube. All one can say is that equipment in which adapters can be so readily transposed, mislabelled or mishandled is subject to improvement. In 1947 Honor[4] reported his experiences with a newly designed double lumen tube, the merits of which seem worthy of presentation here.

The Honor tube is made of a plastic, Geon polyvinyl chloride, impregnated with a nontoxic radiopaque material. The larger lumen for suction has a bore equivalent to large-sized French catheters (Nos. 12-14-16-18). The wall is slightly thinner than that of the Miller-Abbott tubing. The smaller lumen connected to the balloon just admits a No. 18 or 19 needle. The two tubes are extruded at once from a single die, giving the double lumen tubing a smooth contour. The arrangement of the metal adapters is conducive to simple interpretation, as well as simple care (Fig. 5).

This tube fulfills all the requirements originally set down by Abbott and Johnson[1]: there are two lumens, one for aspiration of intestinal contents and the other to introduce air or mercury into the balloon; it is moderately flexible but doesn't kink or collapse on suction; it is nontoxic and radiopaque. In addition, it withstands boiling without rapid deterioration; it is relatively inexpensive, and intestinal odors can be removed by washing.

Although to date our experience with the small-sized Honor tube in infants and children is a small one, we are eminently satisfied with its performance. Repetitions of the rare complication of intestinal intubation described above have not occurred and seem unlikely to occur with this arrangement of adapters and the size of the smaller lumen.

Summary

A recapitulation is made of some of the more common complications which have been encountered in the use of the Miller-Abbott tube, especially in children.

The case of a rare and serious complication following intestinal intubation in a nine-year-old boy is presented.

The merits of the Honor tube are discussed as a means of avoiding such a serious complication.

Discussion

Dr. Gilbert Cottam: I would like to ask about the diagnosis of the boy in the case. He had a chest infiltration, a generalized peritonitis and a ruptured appendix, but I am wondering if a diagnosis of actinomycosis might not have been considered.

Dr. Sivertsen: I am reluctant to say anything about this paper. It has been my unfortunate experience to have had two Miller-Abbott tubes become knotted in the intestinal tract. The first case was that of a fourteen-year-old boy from whom we were able to remove the tube without difficulty. The other was an eighty-two-year-old lady who had had a resection of the bowel because of obstruction. The tube became knotted at the end near the sac or bulb which receives the mercury, gas or air. In this case the tube itself was so tightly knotted that the air in the bulb could not be expelled. Consequently, it was with difficulty that we were able to pull it through

the intestinal tract. It became a question, before this was accomplished, whether or no we should operate to relieve the obstruction. However, we were finally able to remove it. She got along very well for four or five days, but on the sixth day after removal she died, possibly because of intussusception. We were not able to obtain a postmortem examination.

Also, I am reluctant to say much about mercury. I was the first to use it in the Miller-Abbott tube, as valuable in passing the tube through the pyloric end of the stomach. I think you will find the idea was given to Dr. Wangensteen in 1941, and he has given me credit for this original idea in the second edition of his book on intestinal obstruction.

Doctor Cottam: I should like to tell Dr. Sivertsen about a description of a diverticulum of the pharynx which led to death, in which the doctors used mercury, thinking that the obstruction caused by a diverticulum was of a different nature. At autopsy, a large amount of unpassed mercury was found. This was the famous case reported by Dr. Abraham Ludlow, surgeon, in 1767. (See my article in Pharyngeal diverticula in Minnesota Medicine, April, 1934, pp. 222-226.)

ACOUSTIC NEUROMAS

WILLIAM T. PEYTON, M.D.
Minneapolis, Minnesota

The treatment of acoustic neuromas has undergone a gradual evolution since the first attempt was made by McBurney[9] in 1891 to remove a cerebellopontine angle tumor. Acoustic neuromas are usually one of the most easily diagnosed intracranial tumors, yet patients with these tumors still come for operation in the final stages of their untreated evolution. In these late stages, not only is the risk of removal enhanced but the residual sequellae are more severe. Therefore, a review of some of the features of this tumor and a report on personal experience in its treatment should be of value.

Gross Pathology

Acoustic neuromas apparently arise in that part of the eighth nerve which lies in the internal auditory canal. As they grow and expand, they protrude through the porus acousticus into the pontine cistern.

Because they grow slowly and gradually displace the surrounding structures in the cerebellopontine angle, they may attain a surprisingly large size, notwithstanding the small space in which they originate. Weight is not frequently determined because they are removed piecemeal with curet and brain sucker, but one weighing 154 grams was reported by Sachs.[13] To obtain such size they displace the pons, medulla and cerebellum, becoming adherent and embedded in them. The tumor erodes the petrous pyramid and projects itself into every available crevice, including an extension through the tentorial notch. Thus it eventually occludes the cisterna at the tentorial notch and blocks the cerebrospinal fluid as it passes upward to be absorbed over the surface of the cerebral hemispheres. Intracranial pressure rises, and death occurs.

Symptoms

In the typical case, as one might expect, there is a chronological progression of symptoms. At first only the eighth nerve is involved; later, the function of the cranial nerves in the neighborhood and then the brain stem and cerebellum are affected, and finally symptoms of increased intracranial pressure are superimposed. Early irritation of the eighth nerve produces tinnitus aurium. Compression and destruction of the eighth nerve produces loss of hearing on the involved side. The cranial nerves in the angle become involved, especially the fifth nerve. Decreased corneal reflex on the side involved is, as a rule, the earliest finding in addition to disturbed eighth nerve function. Later, signs of cerebellar dysfunction appear, and eventually there is papilledema.

Differential Diagnosis

Other lesions, neoplastic, vascular or degenerative, which occur in the cerebellopontine angle may simulate acoustic neuromas. The differentiation of these lesions is often difficult, and sometimes only after exploration of the angle is the true nature of the lesion determined.

Treatment

Surgical removal, partial or complete, is now recognized as the only proper treatment for acoustic neuroma. Surgery in the treatment of acoustic neuromas has undergone a gradual evolution, from a very crude finger enucleation to partial removal by intracapsular enucleation, and finally to total enucleation, which seems to be more or less the operation of preference with neurosurgeons today.

When McBurney[9] attempted to remove one of these tumors, and for many years, thereafter, surgery for brain tumors was very unsatisfactory, and especially so for tumors of the posterior fossa. Most operations at that time were for tumors of the cerebrum in the region of the motor cortex where the danger of operation was lowest.[1,16] After this early unfavorable experience it was not until about 1905 that surgeons again became less reluctant to operate for tumors of the cerebellum.[14]

The operative mortality reported for finger enucleation of angle tumors was 67 to 87 per cent.[6,12,15,16,17] Cushing[2] operated upon his first case of acoustic neuroma in 1906 and began a fundamental revision in the surgery for acoustic neuroma when he performed an intracapsular enucleation of the growth. Mortality was immediately reduced by this intracapsular enucleation until, with increasing experience and modifications in technique the mortality was, in Cushing's last seventy-six cases, only 8 per cent. Many general improvements in neurosurgical technique contributed to this improvement. A few of the more important are (1) bilateral cerebellar exposure through a cross bow incision (1905); (2) release of intracranial pressure by tapping the lateral ventricle during operation, which was introduced in 1903

Abbreviated from Staff Meeting Bulletin Hospitals of the University of Minnesota, 19:301-314, February 27, 1948.
From the Department of Surgery, Division of Neurosurgery, University of Minnesota.

and became routine by 1910; (3) use of suction instead of sponges to evacuate blood and fluid from the wound; (4) silver clips to occlude bleeding vessels (1909), and (5) late in the period, 1926, introduction of high frequency cautery in neurosurgery.

Dandy[3] in 1922 reported an operation for total removal of acoustic tumors which was an extension of Cushing's intracapsular removal, to include total removal of the capsule after the content had first been removed with a curet. Again in 1925,[4] and also in 1934,[5] Dandy reported improvements in this operation.

Olivecrona[10] began to perform Dandy's radical removal in 1931 and has become one of the most enthusiastic advocates of total removal.[11]

With the partial intracapsular removal of Cushing there were many recurrences within three or four years after operation, and in some, not enough of the upper part of the tumor was removed to re-establish the flow of cerebrospinal fluid, making early reoperation necessary.

With total removal, recurrence does not occur, but the technique is more difficult, especially when the tumor is large and adherent to the brain stem. It is very difficult to remove totally a large acoustic neuroma and preserve the seventh nerve.

The operative mortality reported for Cushing's intracapsular removal is 8 to 28 per cent,[2,8,10,11] and for total removal, 7 to 19 per cent.[7,11,12]

It is the policy of this author to remove acoustic neuromas totally if this is technically possible, but it still seems to be advisable to be content with partial removal of some of the very large tumors which are very adherent to the brain stem, and also of some of those with extreme erosion of temporal bone.

Since 1940 the author has done fourteen total removals with three postoperative deaths, a mortality of 21 per cent. The facial nerve was preserved anatomically in three cases, and there is good function of it in two of the patients. The other patient had not recovered facial nerve function when last seen.

Discussion

Dr. Harold Buchstein: The acoustic neuroma, in many ways, is the most interesting of intracranial tumors. It is a benign lesion. It is so situated that it produces quite a characteristic syndrome which permits its recognition in an early stage. As a result, neurosurgeons have expanded a good deal of effort in developing the technique of surgical treatment of this lesion. I should like to commend Dr. Peyton on his results in the treatment of this tumor. His figures are admirable indeed and certainly compare very favorably with other published series. Usually a tumor of the acoustic nerve does not present vertigo as a prominent complaint. Tinnitis tends to disappear with time. When we see these patients, their complaint is one of deafness and cerebellar difficulty, or a complaint relating to increased intracranial pressure.

Dr. Wallace P. Ritchie: I feel very fortunate, not only in having heard Dr. Peyton's discussion, but also because everything worth while that I know about neuromas I have learned from Dr. Peyton. No matter what your surgical specialty may be, I am sure that Dr. Peyton's extremely remarkable results are obvious. If there is any operation in neurosurgery which requires a top performance not only of the surgeon, but of his assistants, the nursing staff, and the anesthesiologist, it is in this particular operation.

I wish to add one comment in regard to the facial paralysis which follows many of these operations. It is very disfiguring particularly to women. I believe the method of choice is to do a facial and seventh nerve anastamosis. Inasmuch as it takes some months for the nerve to regenerate so that the face will assume a more symmetrical attitude, I believe that it is well to insert, at the same time, a fascial graft from the temporal muscles to the corner of the eye and the corner of the mouth. In this way a patient may return to work a great deal sooner, and will not be embarrassed by the disfigurement of a full facial paralysis.

Dr. Horace Scott: One question: What is the differential diagnosis between Ménière's syndrome and acoustic neuromas?

Dr. Peyton: Bilateral acoustic neuromas are present in about 3 or 4 per cent of all acoustic neuromas, and they occur in young people who have generalized neurofibromatosis. In Dandy's 154 cases, the neuromas were bilateral in 4 per cent. In our relatively small group they have been more numerous, but this is no doubt due to wide variation of chance in a small series. We have had one case in which bilateral tumors were found at autopsy, and a second in which an acoustic neuroma was removed from one side, and the patient now has symptoms and signs of a second tumor on the other side.

The differential diagnosis between Ménière's disease and a small acoustic neuroma is at times very difficult. But, in general, between the attacks of Ménière's disease there are no symptoms or findings except loss of eighth nerve function. In acoustic neuroma, symptoms are apt to be continuous; in Ménière's disease, they are apt to be intermittent. The acoustic neuroma progresses to involve other nerves and structures in the cerebellopontine angle.

There are lesions which occur in the cerebellopontine

(Continued on Page 1032)

Reports and Announcements

AMA INTERIM MEETING

The second AMA Interim Meeting will be held in St. Louis, Missouri, November 30 to noon December 3, 1948.

The first national Medical Public Relations Conference will be held at the Statler Hotel on Saturday evening, November 27 under the sponsorship of the AMA. The annual meeting of Editors and Secretaries of the state medical associations will be held on Sunday and Monday, November 28 and 29, preceding the AMA meeting.

As was the case last year in Cleveland, the scientific program of the Interim Session is planned especially for general practitioners. A wide variety of clinical conferences and exhibits of clinical and pathological material will be correlated with the lecture meetings.

Members planning to attend the St. Louis meeting are urged to make use of the registration form which will appear every two weeks in the AMA *Journal*. Requests for reservations should be received before November 9, 1948.

AMERICAN COLLEGE OF SURGEONS HOSPITAL CONFERENCE

The twenty-seventh annual Hospital Standardization Conference will be held at the Biltmore Hotel, Los Angeles, from October 18 to 22, in conjunction with the thirty-fourth annual Clinical Congress of the American College of Surgeons, according to an announcement by Dr. Malcolm T. MacEachern, Associate Director and Chairman of the Administrative Board. A galaxy of hospital authorities from all parts of the United States and Canada will participate as speakers and discussion leaders in the five-day program, the last day of which, Friday, October 22, will be devoted to study tours of hospitals in Los Angeles and vicinity with the co-operation of the Southern California Hospital Council, of which Paul C. Elliott, Superintendent, Hollywood Presbyterian Hospital, is President. The hospital representatives are invited to attend the meetings of the Clinical Congress.

NATIONAL SOCIETY FOR CRIPPLED CHILDREN AND ADULTS

The 28th annual convention of the National Society for Crippled Children and Adults, Inc., will be held at the LaSalle Hotel, Chicago, November 15-17, 1948.

Many outstanding speakers in the fields of medicine, health and education will be on hand to present facts on progress in work with the handicapped during the past year, according to Lawrence J. Linck, executive director.

The convention will be attended by physicians, therapists, educators, workers with the handicapped and representatives of National Society's more than 2,000 state and local units throughout the United States, Canada, Alaska and Hawaii.

OMAHA MID-WEST CLINICAL SOCIETY

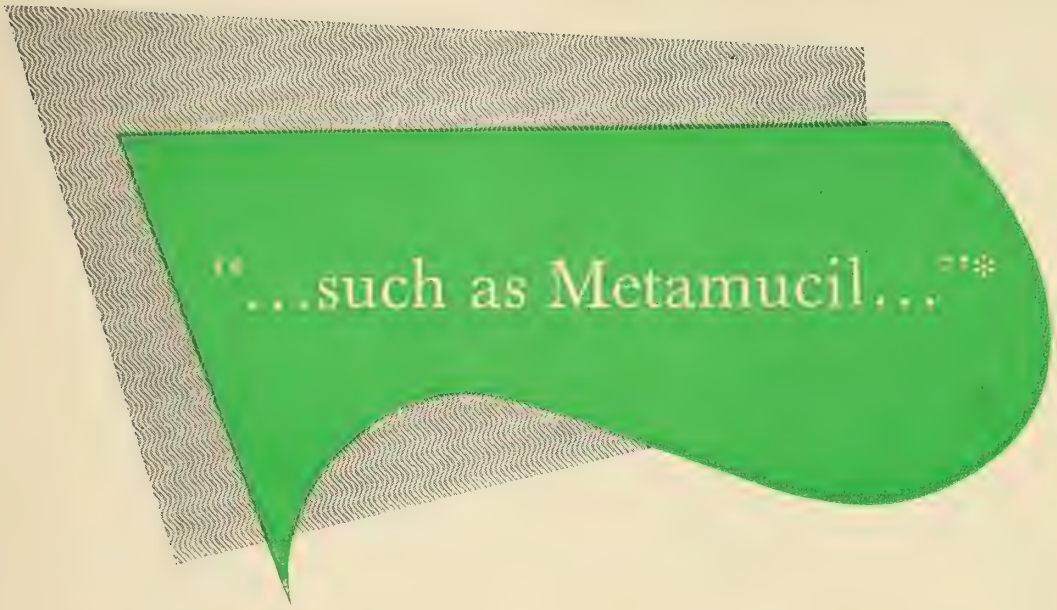
The Omaha Mid-West Clinical Society will hold its sixteenth annual assembly at the Hotel Paxton, Omaha, Nebraska, October 25 to 29, inclusive.

The television projection of a hospital clinic in three rooms of the Paxton Hotel will be an outstanding innovation. On Friday morning, there will be a clinico-pathologic conference and a panel discussion on "The Doctor in Court." Six outstanding physicians and attorneys will discuss such subjects as: (1) The Medical Expert Witness in Casualty Cases; (2) The Psychiatrist in Civil and Criminal Cases; (3) The Pseudo-Medical Expert Witness; (4) The Minnesota Medical Testimony Plan; and (5) the Necessity for Reform in Court Procedure Governing Medical Testimony.

Further information may be obtained by writing the Omaha Mid-West Clinical Society, 1031 Medical Arts Building, Omaha 2, Nebraska.

VAN METER PRIZE AWARD

The American Goiter Association again offers the Van Meter Prize Award of Three Hundred Dollars and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The Award will be made at the annual meeting of the Association which will be held in Madison, Wisconsin, May 26, 27, and 28, 1949, providing essays of sufficient merit are presented in competition.



The competing essays may cover either clinical or research investigations; should not exceed three thousand words in length; must be presented in English; and a typewritten double spaced copy sent to the Corresponding Secretary, Dr. T. C. Davison, 207 Doctors Building, Atlanta 3, Georgia, not later than March 15, 1949. The committee, that will review the manuscripts, is composed of men well qualified to judge the merits of the competing essays.

A place will be reserved on the program of the annual meeting for presentation of the Prize Award Essay by the author, if it is possible for him to attend. The essay will be published in the annual Proceedings of the Association. This will not prevent its further publication, however, in any journal selected by the author.

UROLOGY AWARD

The American Urological Association offers an annual award of $1,000.00 (first prize of $500.00, second prize, $300.00, and third prize, $200.00) for essays on the result of some clinical or laboratory research in Urology. Competition shall be limited to urologists who have been in such specific practice for not more than five years and to residents in urology in recognized hospitals.

(Continued on Page 1030)

For the treatment of the spastic colon the author suggests diet, elimination of the nervous element and "bulk producers." As examples of these he lists "agar-agar, in finely powdered form, in flakes, or in cereal-like form; derivatives of psyllium seed, such as Metamucil . . . ."*

METAMUCIL "SMOOTHAGE" IN CONSTIPATION

—"encourages elimination by the formation of a soft, plastic, water-retaining gelatinous residue in the lower bowel."†

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

Metamucil is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent.

SEARLE RESEARCH IN THE SERVICE OF MEDICINE

Metamucil is the registered trademark of G. D. Searle & Co., Chicago 80, Illinois.

*Glafke, W. H.: Spastic Colon, M. Clin. North America 26:805 (May) 1942.

†Council on Pharmacy and Chemistry: New and Nonofficial Remedies, 1947, Philadelphia, J. P. Lippincott Company, 1947, p. 320.

UROLOGY AWARD

(Continued from Page 1028)

The first prize essay will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Biltmore Hotel in Los Angeles, May 16-19, 1949.

For full particulars write the Secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis 3, Tennessee. Essays must be in his hands before February 15, 1949.

COURSE IN CLINICAL ALLERGY

The Northwestern University Medical School will conduct a five-day course in clinical allergy at Thorne Hall, in the medical school in Chicago, from October 25 to 29, 1948. The course is under the sponsorship of the American Academy of Allergy. Lectures and demonstrations on the many phases of allergy by members of the Northwestern University Medical School faculty will occupy mornings and afternoons. A dinner and round-table discussion will be held on Tuesday, October 26.

The fee of $45 includes the price of the dinner and mimeographed notes. Attendance is limited to members of the profession and a limited number of residents and interns. Inquiries should be addressed to Dr. Samuel M. Feinberg, Northwestern University Medical School, 303 East Chicago Avenue, Chicago, Illinois.

COURSES IN PSYCHOSOMATIC MEDICINE TRAUMATIC SURGERY AND ORTHOPEDICS

An intensive two-week course in psychosomatic medicine will be given at the Center for Continuation Study of the University of Minnesota. The course is designed to assist the general physician in the diagnosis and treatment of psychosomatic problems. The course will be presented during the two-week period from September 20 to October 2. Enrollment will be limited to twenty-five physicians, because much of the material will be presented by means of group discussions and supervised clinical work.

The Department of Postgraduate Medical Education also announces a course in traumatic surgery and orthopedics, to be given for general physicians, October 7 to 9, in the Center for Continuation Study of the University of Minnesota. Registration for this course will be limited to 100 physicians.

COURSE ON TUBERCULOSIS

A course on tuberculosis and other diseases of the chest, for general practitioners, will be held October 18, 19, and 20 at the University of Minnesota's Center for Continuation Study in Minneapolis.

The American Trudeau Society, the University of Minnesota and the state Christmas Seal organization are co-sponsors of the course. County Christmas Seal associations are also participating by appropriating sums towards the expenses of two doctors from each district medical society to attend the course.

Subjects to be covered in the three-day meet, which will be a complete and condensed survey of tuberculosis and other diseases of the chest, are: physical examination in the diagnosis of tuberculosis; differential diagnosis of hemoptysis, pleurisy and pleural effusion; skin test in the diagnosis of chest diseases; laboratory aids in the diagnosis of diseases of the chest; family physician and chest x-ray surveys; chronic bronchitis and bronchiectasis of the lungs; fungus diseases of the chest; immunization in tuberculosis; antibiotics and chemotherapy in the treatment of tuberculosis.

TWIN CITIES NOW RESERVE MEDICAL CENTER

Colonel Raymond R. Tourtillott, State Senior Instructor for the Organized Reserve Corps, in a special release to MINNESOTA MEDICINE pays tribute to the efforts of Twin Cities Medical Department Officers. He states,

"Through aggressive organization and a show of interest by all concerned, the Organized Reserve Medical Units of the Twin Cities have now built their strength to where they may claim to be one of the most highly concentrated Medical organizations in the Northwest.

"Meeting at Fort Snelling, the organization contains eleven separate units and 617 members.

"The Units are headed by a Headquarters Hospital Center and number a General and a Station Hospital among them. There are also two large laboratory units, a Mobile Surgical Hospital, Medical Collecting Co., Malaria Survey Detachment, Malaria Control Detachment and a Medical Base Depot Co. A medical composite group contains additional medical officers with a wide variety of technical training.

"These units were organized by local Reserve Officers who served in World War II and are determined to support National Security through their efforts. The units are strong in numbers and have a healthy turnout at training periods. A more vigorous training program will get under way as soon as alterations are completed in the Medical Center at Fort Snelling, the Headquarters of these Units.

"Credit for organizing these Units goes to the Unit Commanders. As they do not wish their efforts to be connected with publicity, the Army bows to their modesty and patriotism and salutes their achievements. We can look to the words of Daniel Webster, 'God grants liberty only to those who love it, and are always ready to guard and defend it.'"

MINNESOTA PUBLIC HEALTH CONFERENCE

Doctors in all branches of the profession are cordially invited by the Minnesota Public Health Conference to attend the all-day session of the Conference at the Saint Paul Hotel, Saint Paul, on Friday, October 8, 1948.

Of special interest will be the noon luncheon for doctors and health officers, when the Minnesota Board of Health will meet to discuss with those present state and local health problems.

In charge will be Dr. T. B. Magath of Rochester, who is Board of Health president. Other Board members include Dr. Ruth S. Boynton, vice president; Dr. A. J. Chesley, secretary and executive officer; Dr. C. V. Netz; Mr. F. E. Bass; and Dr. T. H. Sweetser; all of whom are from Minneapolis; Dr. Sidney Hedeen of

St. Paul; Dr. F. W. Behmler of Morris; Dr. W. L. Webb, who lives in Fairmont; and L. M. Thompson of Little Falls.

This session will give all doctors concerned with public health a chance to bring their problems up for general discussion. Matters such as full-time health units will probably be aired.

At the general afternoon session, Dr. Donald A. Dukelow of Minneapolis, Conference executive secretary, will lead the panel discussion on the Pros and Cons of Local Health Services for Minnesota. Discussants will be Howard Ottinger and Harry L. Wahlstrand of the State Legislature, Louis C. Dorweiler who directs the Legislative Research Committee, and J. S. Jones of the Farm Bureau who serves as second vice president of the Minnesota Committee on Local Health Services.

Evening speaker will be Miss Katherine F. Lenroot chief of the United States Children's Bureau. Toastmaster will be Dr. Mario Fischer of Duluth.

All doctors interested in public health are eligible to become associate members of the Minnesota Public Health Conference, upon payment of a one-dollar membership fee. Doctors active in public health work of any kind may become active members of the Conference, with dues of two dollars a year. Memberships may be obtained at the Conference meeting, or from Dr. Donald A. Dukelow, Citizen's Aid Building, Minneapolis.

HEALTH DAYS

Health Days are scheduled for every section of Minnesota this fall, the Minnesota Department of Health announces.

Starting in southwestern Minnesota last February, when more than a thousand people assembled for a Health Day in Worthington, the idea of getting people together to discuss the health needs of their communities has spread all over the state.

On September 9 a very successful Health Day was held at Willmar for Traverse, Stevens, Pope, Swift, Lac Qui Parle, Chippewa, Yellow Medicine, Renville, Lincoln, Lyon, Redwood, Kandiyohi, Meeker, and Big Stone counties.

Plans are under way for the following Health Days:

September 29 at Fergus Falls for Clay, Becker, Otter Tail, Wilkin, Grant, and Douglas counties.

October 7 at Crookston for Kittson, Roseau, Marshall, Polk, Red Lake, Pennington, Lake of the Woods, Mahnomen, and Norman counties.

October 13 at Mankato for McLeod, Carver, Scott, Sibley, Le Sueur, Nicollet, Brown, Blue Earth, Watonwan, Waseca, Martin, and Faribault counties.

October 15 at Duluth for Lake, Cook, Carlton, Pine, and St. Louis counties.

Governor Youngdahl is speaking at evening meetings at each of these Health Days. Programs will include keynote speeches in the morning, also group discussion on health problems of local concern. Health films will be shown in the afternoon, panels will discuss community health problems, and there will be several ten-minute talks by local people. High school bands will furnish

"An excellent simple presumptive test for routine use in the diagnosis of diabetes."[1]

CLINITEST

THE TABLET *NO-HEATING* METHOD FOR DETECTION OF URINE-SUGAR

SIMPLE TECHNIC—"My experience with Clinitest has convinced me beyond a shadow of a doubt that they are *the simplest* from the technical standpoint . . ."[2]

SELF-GENERATING HEAT—"The reagent tablet, known as the Clinitest Urine Sugar Tablet . . . generates heat when dissolved and the use of externally applied heat is not required . . ."[1]

Clinitest—simple, speedy, compact, convenient—is distributed through regular drug and medical supply channels.

entertainment at the evening meetings before the governor speaks.

Sponsoring groups for the fall health days are the Minnesota State Medical Association and its Woman's Auxiliary. The Minnesota Department of Health is assisting in organization and publicity.

It is the intention that all these health days will be followed, as in Southwestern Minnesota, by the formation of local or county health councils.

RIGLER LECTURE IN RADIOLOGY

Dr. Merrill C. Sosman, professor of radiology at Harvard university, will deliver the annual Dr. Leo G. Rigler lecture in radiology at the University of Minnesota Thursday, October 28, at 8 p.m. in the Minnesota Museum of Natural History auditorium.

Dr. Sosman, who will speak on the subject "Roentgenological Aspects of Heart Disease," is the contributor of numerous articles on the diagnosis and treatment of diseases or tumors by x-ray to scientific publications.

The annual Rigler lectureship was established in 1944 by colleagues, former students and friends of the roentgenologist in recognition of his contributions to teaching and research in radiology. He has been chief of the department of radiology at the University of Minnesota since 1926.

During the week of Dr. Sosman's lecture, from October 25-30, a continuation course in cardiovascular roentgenology, designed primarily for radiologists but open also to a limited number of internists, pediatricians and surgeons, will be held at the University's Center for Continuation Study.

CRIPPLED CHILDREN CLINIC SCHEDULE

Clinics for crippled children are being held in ten Minnesota cities this fall to serve residents of forty-three counties. The clinics are sponsored by the Crippled Children Services of the Medical Services Unit of the Division of Social Welfare. All clinics are held on Saturday except the two Friday ones indicated in the 1948 schedule which follows:

Place	*Date*	*Building*	*Counties*
Winona	9-11-48	Central School	Winona, Houston, Wabasha, Olmsted, Fillmore
Fergus Falls	9-18-48	High School	Ottertail, Wilkin
Bemidji	9-25-48	High School	Beltrami, Lake of the Woods, Clearwater, Hubbard
Willmar	10-8-48 (Friday)	Auditorium	Kandiyohi, Meeker, Swift, McLeod, Chippewa, Renville
Marshall	10-9-48	High School	Lyon, Lincoln, Redwood, Yellow Medicine, Lac qui Parle
Virginia	10-16-48	Technical High School	St. Louis
Crookston	10-23-48	High School	Polk, Mahnomen, Norman
Cambridge	10-29-48 (Friday)	Epileptic Colony Hospital	Isanti, Anoka, Kanabec, Chisago, Mille Lacs
Little Falls	10-30-48	High School	Morrison, Todd, Mille Lacs
Mankato	11-6-48	Franklin School	Blue Earth, Sibley, Nicollet, Le Sueur, Watonwan, Brown, Waseca, Martin, Faribault

RED RIVER VALLEY SOCIETY

A special summer meeting of the Red River Valley Medical Society, with nearly fifty physicians in attendance, was held in Thief River Falls on July 23.

Scientific papers were presented by Dr. Thomas J. Dry and Dr. Lawrence M. Randall, both from the Mayo Clinic in Rochester. The Blue Shield plan was explained in detail by Arthur Calvin, executive secretary of the Blue Cross organization. Also appearing on the program was Manley Brist, attorney for the Minnesota State Medical Association.

In charge of the program was Dr. Martin Bechtel, Warren, president of the society, assisted by Dr. Russell Sather of Crookston, secretary.

CLINICAL-PATHOLOGICAL CONFERENCE

(Continued from Page 1004)

edema in the remaining eighty-four patients of the entire study.

Of twenty-nine patients with hydronephrosis of varied etiology, twelve were due to benign prostatic hypertrophy and twenty-four had pyelonephritis. Of the twenty-four patients, twenty had bronchopneumonia, while only seventeen other cases of bronchopneumonia were found in the other seventy-six patients in the study. Seventeen out of twenty other serious infectious complications occurred in the pyelonephritic group. Not a single case of the eight patients with primary pyelonephritis was diagnosed properly.

In comparing these findings with studies of others, it should be borne in mind that many patients with serious primary kidney diseases described in our necropsy records were not included in this study, when it was felt that renal failure did not contribute significantly to the causes of death.

angle and give us equally as much difficulty in the differential diagnosis. They are degenerative lesions, vascular lesions, or other tumors in the angle. I might mention the other operations we have performed for lesions in the cerebellopontine angle during the period in which these twenty acoustic neuromas were encountered. There were three cases of meningioma in the angle, two gliomas in the pons, one tuberculous granuloma, one case of aberrant artery which passed around the eighth nerve producing deafness and vertigo, one case of trigeminal neuralgia with loss of hearing on the side of the pain (for this reason rhizotomy was done in the posterior fossa instead of the usual subtemporal rhizotomy), and one case which was explored and nothing found.

Woman's Auxiliary

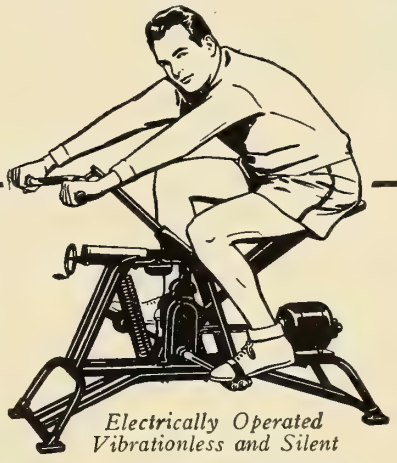
ANNUAL MEETING

On Monday, June 7, the meetings of the Woman's Auxiliary to the Minnesota State Medical Association opened with a Board meeting and luncheon in the Italian Room of the Hotel Radisson, Minneapolis. The president, Mrs. J. A. Thabes, Sr., of Brainerd, presided.

Members of the Hennepin County Medical Auxiliary were hostesses to all visiting women at a tea and reception held in the Woman's Club of Minneapolis on Monday afternoon.

Many physicians and their wives enjoyed the evening at the Hotel Radisson Ballroom on Monday night.

On Tuesday, the twenty-sixth annual meeting of the Woman's Auxiliary was held in the East Room of the Curtis Hotel, Mrs. Thabes presiding. Mrs. Frederick Schaaf, president of the Hennepin County Medical Auxiliary, welcomed those attending and invited them to attend the various functions which had been planned for all guests. Mrs. S. S. Hesselgrave responded and thanked Mrs. Schaaf and the Hennepin County Auxiliary for their hospitality.



Annual reports of chairmen, officers and county auxiliary presidents followed. Mrs. Harold Wahlquist, president-elect, reported twenty-six organized counties and six counties still unorganized with several planning organizational meetings in the fall. Minnesota now has 1,632 members, of which 214 are new members.

The following officers were elected: President-elect, Mrs. H. E. Bakkila, Duluth; First Vice President, Mrs. Charles W. Waas, St. Paul; Second Vice President, Mrs. John Dordal, Sacred Heart; Third Vice President, Mrs. T. N. Fleming, St. Cloud; Fourth Vice President, Mrs. Ernest M. Hammes, St. Paul; Recording Secretary, Mrs. W. A. Merritt, Rochester; Treasurer, Mrs. George Penn, Mankato, and Auditor, Mrs. Henry W. Quist, Minneapolis.

It was voted unanimously to collect a sum from all County Auxiliaries to be turned into the State Auxiliary for the Dr. William A. O'Brien Memorial Fund.

The annual luncheon was held in the Wedgewood Room of the Curtis Hotel. Mrs. Thabes presented the newly elected officers. Mrs. Martin Nordland of Minneapolis presented the president's pin to Mrs. Harold Wahlquist who outlined Auxiliary objectives for the coming year. She also read the following communication from the Council of the Minnesota State Medical

ACTION of the body muscles keeps the body fit the EXERCYCLE* way

Electrically Operated
Vibrationless and Silent

● **Many physicians use Exercycle to limber up, strengthen abdominal muscles, accelerate muscular activity. Just get on, turn the switch and enjoy the beneficial motions of horseback riding, rowing, cycling, swimming. Also excellent for establishing a regimen for patients who are limited as to the amount or kind of activity they can take. Pleasant, convenient, adaptable. Enjoyed by men and women alike. Send for interesting brochure.**

Association: "The Council approved a budget for the expenses involved in conducting a two-day School of Instruction this fall for county presidents and committee chairmen of the Auxiliary who will assume leadership in the development of Public Health Days throughout Minnesota from a planning and public relations standpoint. It also approved the expenses involved in sending out a quarterly News Letter to Auxiliary members."

Mrs. J. M. Neal, Program Chairman, of Minneapolis introduced the guest speaker, Dr. Stewart C. Thomson, Associate Professor, School of Public Health, University of Minnesota, whose topic was "Man's Fight Against Disease."

At the banquet of the State Association on Tuesday evening, Dr. Ralph Creighton, president of the Hennepin County Medical Society, presided and presented Mrs. Wahlquist who addressed the group.

The traditional breakfast given at ten o'clock on Wednesday morning by the members of the Hennepin County Auxiliary was a fine social climax to a busy three days. Everyone enjoyed the spontaneity with which Mrs. Leonard Arling read for us.

Members of the State Auxiliary are grateful to their gracious hostesses of Hennepin County for the charming and generous hospitality extended during their stay in Minneapolis.

Mrs. Harold Satterlee
Retiring Secretary

FALL ACTIVITIES

The Board members of the Woman's Auxiliary began making ambitious plans for an extremely busy year at the post-convention Board meeting in June. Details are being completed for a two-day School of Instruction in September and Area Health Days which are being co-sponsored by the Auxiliary, the Minnesota State Medical Association and the State Department of Health. The Health Days will be similar to the one held at Worthington last February with round-table discussions, health movies, exhibits and an evening address by the Governor. Wives of physicians in all communities will be in key positions assisting with promotional plans.

The School of Instruction to be held September 24 and 25 at the Radisson Hotel in conjunction with the fall Board session for representatives of the twenty-six organized counties is a new experiment. The program will be planned to assist members in knowing how to relate themselves better as wives of physicians and leaders in health to their communities. Round-tables on community health planning, legislation, rural health problems will be conducted by experts in their field, including Dr. Gaylord Anderson, Director of the School of Public Health, Dr. John O. Christianson, Superintendent of the School of Agriculture, both of the University of Minnesota, Mr. L. W. Rember, Executive Assistant in charge of Public Relations, AMA, and Mrs. Luther H. Kice, President of the Woman's Auxiliary to the American Medical Association. The State Association is graciously and indispensably assisting with details.

The MSMA is providing the Auxiliary Board two means to keep auxiliary members informed this year, and to be a *good* auxiliary member one must be informed. Every month we shall have a page in Minnesota Medicine. This is journal copy number one. In addition, the Association is generously underwriting a quarterly News Letter. Members received the first copy in August.

Mrs. Harold F. Wahlquist
President

MRS. JAMES BLAKE

It is with deep regret that the Woman's Auxiliary of the Minnesota State Medical Association announces the death of Mrs. James Blake of Hopkins, which occurred at her home on Wednesday, July 21, following a heart attack.

The Auxiliaries of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association have lost a valuable friend and counselor. Mrs. Blake was a past president of all three organizations. A pioneer and civic leader in her community, Mrs. Blake, although an invalid for four years previous to her death, did not allow her illness to lessen her enthusiasm for Auxiliary work. Those who sought her advice valued her wisdom and sound judgment.

Agnes MacDonald Blake was born in Mankato on December 16, 1878, where she attended school. She was graduated from Mankato State Teachers College and later taught in New Ulm. She was married to Dr. James Blake of Hopkins on June 20, 1904, and resided in Hopkins until her death.

Mrs. Blake was devoted to her family, although her efficiency and boundless energy enabled her to become a leader in community affairs. Not only did she devote considerable time to social and professional phases of Auxiliary work, but she also was a leader in the Minnesota Federation of Women's Clubs, in the Public Health and Nursing movements, and, during both World Wars, in Red Cross and war relief work.

Following World War I Mrs. Blake organized a civic-betterment group, the Agnes Blake Study Club, which was responsible for many improvements in recreation, park and civic facilities for Hopkins.

In spite of her many achievements in public life, Mrs. Blake was primarily a homemaker. She had six children: two daughters—Jeannette, a nurse at the Veterans Hospital, and Mrs. Charles Adams of Springfield, Illinois, and four sons—James A., Allen, and Paul, all physicians practicing in Hopkins, and Donald, who was killed while serving in the United States Army, stationed in California.

The Auxiliary extends its deepest sympathy to Doctor James Blake and his family. The keen loss which they feel is shared by every member of the organization. The vacancy created by her passing will be indeed difficult to fill.

Marie E. Hesselgrave

In Memoriam

HERBERT BENJAMIN ALLEN

Dr. H. B. Allen, chief physician for the George A. Hormel Company at Austin, Minnesota, died suddenly, August 24, 1948. He was forty-one years of age.

Born in Slayton, Minnesota, September 20, 1906, he was brought up in Staples where he attended grade and high school. He graduated from the University of Minnesota Medical School in 1937 and became associated with the Hormel Packing Plant the same year.

Dr. Allen is survived by his wife, Marion, and daughter, Lani. A brother, Frank Allen, lives in Duluth and a sister in Minneapolis.

LUTHER NOBLE BERG

Dr. L. N. Berg of Montevideo, Minnesota, passed away on June 2, 1948, at the age of sixty-seven.

Dr. Berg was born September 27, 1880, in Yellow Medicine County, Minnesota. He received a B.A. degree from Augsburg College, Minneapolis, in 1902 and his medical degree from the University of Minnesota in 1906. He interned at Ancker Hospital, Saint Paul.

He was a member of the Camp Release District Medical Society, the Minnesota State Medical Association and American Medical Association.

ARTHUR J. G. HENDERSON

Dr. Arthur J. G. Henderson, formerly of Kiester, Minnesota, died of a heart attack on May 16, 1948, at his home in North Saint Paul.

Dr. Henderson was born at Lake Mills, Iowa, on May 3, 1894. He attended St. Olaf College and the University of Minnesota before obtaining his medical degree at the University of Illinois in 1919. His internship was served at the Swedish Hospital in Minneapolis.

He was a member of the Blue Earth Valley Medical Society, the Minnesota State Medical Association and American Medical Association.

THEODORE HOLTAN

Dr. Theodore Holtan passed away at his home in Waterville, Minnesota, August 22, 1948, at the age of sixty-five, following a heart attack.

Dr. Holtan was born in Forest City, Iowa, April 8,

1883. He attended Decorah Institute at Decorah, Iowa, and Hamline University, Saint Paul, before obtaining his medical degree at Marquette University, Milwaukee, in 1911. After interning at Asbury Hospital, Minneapolis, he practiced at Wheaton, Minnesota, from June, 1912, to February, 1918, and then at Kilkenny, Minnesota, until September, 1921. For the past twenty-seven years, he has been practicing his profession in Waterville.

Dr. Holtan was a member of the Nicollet-LeSueur Medical Society, the Minnesota State and American Medical Associations.

He leaves to mourn, his wife and two sons.

JAMES S. REYNOLDS

Dr. James S. Reynolds, former president of Hennepin County Medical Society, and specialist in eye, ear, nose and throat, met an untimely death July 7, 1948, at his country home where he and Mrs. Reynolds were victims of a double murder committed by Mrs. Reynolds' brother.

Dr. Reynolds was born March 15, 1880, at New Hampton, Iowa. He attended Ames College, Iowa, and received his medical degree from the University of Minnesota in 1905. He was a member of the American Medical Association, Minnesota State Medical Association, Hennepin County Medical Society, Minnesota Academy of Ophthalmology and Otolaryngology, of which he was president 1934-35, and a fellow of the American College of Surgeons. Socially, he was a member of Phi Beta Pi fraternity, Rotary Club, University Blue Lodge, Zuhrah Temple of the Shrine, and a Scottish Rite Mason of the highest degree.

"Jim," as everybody called him, was held in high esteem, both personally and professionally, by all who knew him. He was a man among men. He was chief of the eye, ear, nose and throat section at St. Barnabas Hospital, and his passing will be deeply felt.

He is survived by a sister, Mrs. Maude Glazier of New Hampton, Iowa.

ADOLPH A. PASSER

Dr. Adolph A. Passer of Olivia died of a cerebral hemorrhage on August 18, 1948. He was sixty-eight years of age.

Dr. Passer was born at Luverne, Minnesota, on January 3, 1880, the son of the Rev. Ludvig Passer. He obtained an A.B. degree from the University of Minnesota in 1902.

From 1902 to 1904, he was employed as high school teacher in Waseca, and from 1904 to 1907 he held a similar position at Virginia. During the next year he was employed as a drug store clerk at St. Cloud. In 1908, he returned to the University where he graduated in medicine in 1912. His internship was served at Minneapolis General Hospital.

He was a member of Renville County Medical Society and the Minnesota State and American Medical Associations. He was also a member of the local Masonic Lodge.

One of Olivia's prominent citizens and a practitioner there for thirty-five years, Dr. Passer was always active in civic and medical affairs. From 1920 to 1923, he served as president of the village council and, from 1913 to 1923, as county coroner. He was health officer for Olivia and Renville County for many years. He was also a county draft board member in the first World War and was examining physician for the Selective Service in the last war.

On May 15, 1913, Dr. Passer was married to Irene Monk, who survives him.

Dr. Passer was an able physician and his gentle and friendly manner endeared him to his many friends and acquaintances.

GEORGE E. VAUGHAN

Dr. George E. Vaughan of Winnebago, Minnesota, died May 31, 1948, from a pulmonary embolism following an operation at Rochester.

Dr. Vaughan was born September 14, 1865, in Lansing, Minnesota. He attended Pillsbury Academy, the University of Minnesota Medical School and the University of Chicago Medical School.

He began practice in Winnebago in 1907 and continued practice until his retirement in 1939. He is survived by two sons, C. C. Vaughan of Minneapolis and Dr. V. M. Vaughan of Truman, Minnesota.

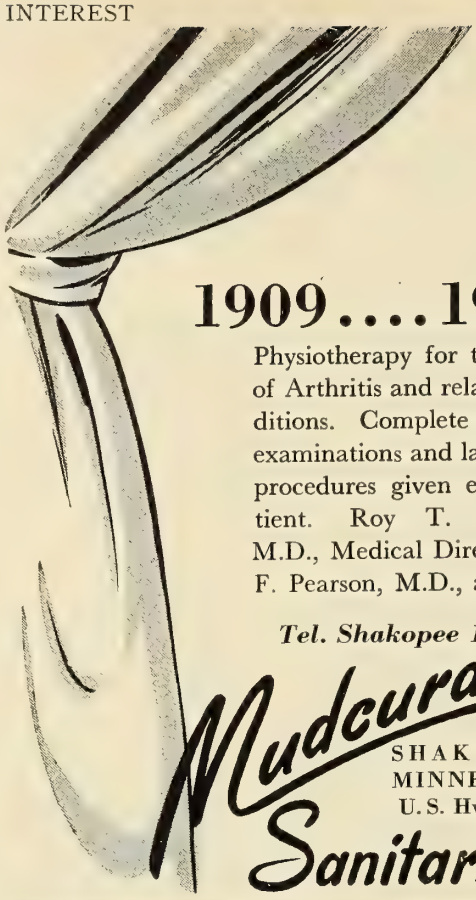
Dr. Abraham Shedlov is retiring from active practice, after twenty-eight years of service as a physician, and will make his home in Long Beach, California, where he will be established after October at 1038 Harding Street. Dr. Shedlov's practice at Fosston, Minnesota, will be taken over by Dr. Hartvig Roholt, formerly of Waverly, Minnesota.

* * *



Announcement has been made that Dr. G. J. Plattes, a former St. Cloud resident, is now associated in practice with Dr. A. F. Giesen in the Minnewaska Clinic in Starbuck. Dr. Plattes, a graduate of the University of Minnesota Medical School in 1944, spent two years at Harper Hospital in Detroit, Michigan, before becoming a medical officer in the navy. Following his discharge from service, he was on the staff of Minneapolis General Hospital.

* * *

Speaking at a convention in July of the American Association of Workers for the Blind, Dr. William L. Benedict, head of the Mayo Clinic Ophthalmology Section, stated that of 419 cornea-transplant operations performed at five eastern hospitals over a five-year period, only 36.4 per cent were successful. The main cause of failure, he said, was that many of the corneal transplants did not remain clear for more than a few months.

* * *

A new staff member of the Interstate Clinic in Red Wing is Dr. Winston R. Miller, who on August 2 became associated with Dr. R. V. Sherman in the department of internal medicine. A graduate of the University of Kansas, where he received M.S. and M.D. degrees and also taught bacteriology for four years, Dr. Miller served in the navy for three years during the war. Following his discharge from service, he was on the medical staff of Henry Ford Hospital in Detroit, Michigan.

Dr. John C. Hays has opened offices at 936 Lowry Medical Arts Building, Saint Paul, for the practice of internal medicine. Dr. Hays graduated from the University of Minnesota in 1943, and took an internship and a year of residency at the Minneapolis General Hospital. After serving in the Medical Corps of the Army for a year and a half, he completed his residency at the U. S. Veterans Hospital in Minneapolis.

* * *

Dr. Olaf Mickelsen, associate professor in the University of Minnesota's laboratory of physiological hygiene, has resigned his position to become chief of the biochemical section in the United States Public Health service nutrition division in Washington, D. C. Dr. Mickelsen has been on the staff of the University of Minnesota since 1940. He will begin his new duties in Washington at once.

* * *

The American Medical Association is building a five-story addition to its headquarters at 535 North Dearborn Street, Chicago. The addition will cost $500,000 and will add about 25 per cent more floor space. Two stories were added in 1936 to the original six-story structure built in 1923, and a three-story wing was added in 1941. Further additional space is required to house the additional activities of the Association.

* * *

Dr. Troy Rollins arrived in Elmore on July 1 to join Dr. Harry Shragg and complete the transfer of the former practice of Dr. A. W. Sommer. The practice, which Dr. Rollins and Dr. Shragg acquired from Dr. Sommer, was conducted alone by Dr. Shragg from January to July, awaiting the completion of Dr. Rollin's internship at Ancker Hospital, Saint Paul. Dr. Sommer is now practicing in Temple, Texas, serving as radiologist with the Scott-White Clinic.

* * *

It was announced in July that two recent University of Minnesota graduates planned to open a medical-dental clinic in Fairmont on September 1. The physician-dentist team is composed of Dr. Jerome L. Behounek, formerly of Marshall, who graduated from the University of Minnesota Medical School in 1945, and Dr. Russell J. Kotval, formerly of Livermore, Iowa, who received his dental degree at the University School of Dentistry this past spring.

* * *

On July 18, Dr. Gunnar Linner announced the opening of new offices at 6614 Lyndale Avenue S., Richfield (Minneapolis). A graduate of the University of Minnesota Medical School, Dr. Linner practiced in south Minneapolis until 1940, when he entered the army. After two years overseas he returned to the United States and served as hospital commander at Camp Ellis, Fort Lewis and Camp McCoy. He was on active duty for seven years.

* * *

In a presentation ceremony sponsored on July 14 by the Lions and Rotary Clubs of St. Peter, Dr. F. P. Strathern, president of the Nicollet County Board of Health, was honored for his services in the fight against tuberculosis. At the ceremony a plaque was presented to him by Dr. E. A. Meyerding, executive secretary of the Minnesota Public Health Association. Dr. Strathern has practiced medicine for nearly fifty years and has headed the Nicollet County Christmas Seal drive for twenty-five years.

* * *

Dr. Gaylord W. Anderson, director of the University of Minnesota School of Public Health, returned to Minneapolis during the middle of July from an eight-week "good will" tour of South American schools of public health. The tour was under the auspices of the U. S. State Department. As a secretary of the Association of the Schools of Public Health in the U. S., Dr. Anderson visited and lectured at schools in Brazil, Argentina and Chile.

"South American doctors," he reported, "are grappling principally with health worries such as tuberculosis, intestinal diseases, nutrition and housing."

* * *

Dr. Magnus C. Peterson has returned to his office as superintendent of the Rochester State Hospital, following a sojourn overseas.

During the past two months Dr. Peterson has visited mental hospitals in Denmark, Sweden and Portugal and presented a paper at the first international conference on psychosurgery held in Lisbon, Portugal, August 3 through 7.

Presentation of the paper at the conference was his main reason for going to Europe. Entitled "Pre-frontal

Lobotomy," the paper was prepared in collaboration with Dr. J. Grafton Love of the Mayo Clinic.

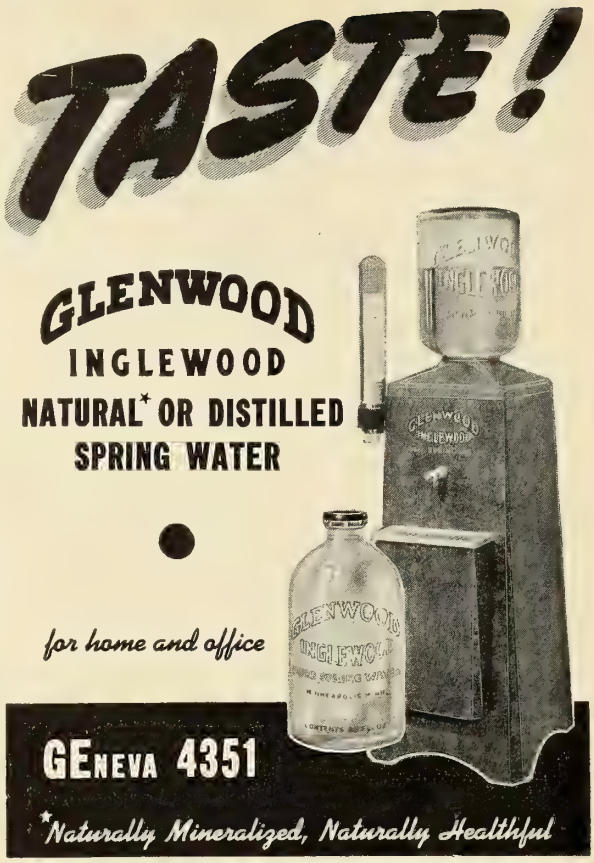
* * *

Dr. Alexander Dumas, clinical assistant professor of psychiatry and neurology at the University of Minnesota, presented the second in a series of radio talks on mental health over Station WREX, Duluth, on July 27. Dr. Dumas spoke on "The Nature and Extent of the Problem." The third talk in the series was given on August 3 by Dr. Roger W. Howell, clinical assistant professor of psychiatry at the University of Minnesota, who spoke on "The Nature and Causes of Mental Illness." The radio series is sponsored by the American Association of University Women as part of a statewide education program.

* * *

Mrs. James Blake, the wife of Dr. James Blake of Hopkins (Minneapolis) and a prominent leader in medical auxiliary affairs, died at her home on July 21. A resident of Hopkins since her marriage in 1904, Mrs. Blake was active in auxiliary work at county, state and national levels. Several years ago she was president of the American Medical Association Auxiliary.

She is survived by her husband; by three sons, Dr. James A. Blake and Dr. Allan Blake, both of Hopkins, and Dr. Paul Blake, stationed at a veterans' hospital; and by two daughters, Mrs. Charles Adams, a nurse in Springfield, Illinois, and Jeanette Blake, of Hopkins. A fourth son, Donald, was killed in service during World War II.



* * *

Dr. Cassius J. Van Slyke has been appointed Director of the National Heart Institute, one of the Institutes of Health in the U. S. Public Health Service. The National Heart Institute was created by Congress in the National Heart Act enacted June 16, 1948. Its program will include the conduct of research, financial aid to outside institutions for research, training of professional personnel and grants-in-aid to the states for heart disease control. Headquarters will be at the National Institute of Health, Bethesda, Maryland. Dr. Van Slyke received his medical degree from the University of Minnesota in 1928 and a commission in the Public Health Service in 1932. Assignments include experimental research at the Venereal Disease Research Laboratory at Stapleton, Staten Island. Since 1945 he has been in charge of the research grants-in-aid and fellowship program of the National Institute of Health.

* * *

Announcement was made in late July that two additional physicians would join the staff of the Austin Clinic in the near future.

Dr. Thomas M. Seery, a graduate of the University of Minnesota Medical School in 1942, planned to arrive in Austin on October 1. Dr. Seery interned at Minneapolis General Hospital and then spent three years in military service. Since receiving his discharge he has studied internal medicine at the Milwaukee County General Hospital and the University of Minnesota Hos-

pitals. In addition to his medical degree, he has a Minnesota master of science degree in pharmacology and bacteriology.

The other physician, Dr. Edward C. Sargent, Jr., will arrive in Austin about January 1, 1949. A graduate of Western Reserve University, in Cleveland, and a veteran of three years of naval service, Dr. Sargent is now completing a term as senior resident in obstetrics and gynecology at the University of Minnesota Hospitals. In Austin his practice will be limited to his specialty.

* * *

BLUE SHIELD NEWS

Number persons covered by Blue Shield, July 31, 1948—34,526
Applications received to date listed over 49,000
Number Blue Shield cases paid, July 15—July 31, 1948— 228
Total for 1948— 1,053
Amount paid on Blue Shield cases, July 15—
July 31, 1948—$ 9,401.45
Total for 1948— 39,574.84

In July, 1948, the Minnesota Blue Shield completed its sixth month of making allowances on Blue Shield cases. At that time a six-month survey was made, and some rather interesting facts and figures were obtained. Of the 832 professional services for which allowances were made, only thirty-five were for appendectomies; however, this accounted for the largest allowance for any surgical procedure, $2,668.75. The greatest number of claims were paid for the removal of tonsils and adenoids. This procedure totaled forty-nine cases in the amount of $1,563,75 (5.20 per cent of all allowances made).

The largest allowance made was $6,727.89 (22.38 per cent) for medical care received by Blue Shield subscribers and dependents who were hospitalized. The attending physician received on the average of $22.57 for each medical case. It is interesting to note that in talking with physicians throughout the state and also with business managers of clinics, it has been stated that the Blue Shield allowance for medical care on the average is more than the physician's usual charge. This is very gratifying. On the other hand, the charges for surgery are greater than the Blue Shield allowance; however, the medical and surgical allowances compensate for each other.

The average amount paid on Blue Shield cases of all types—that is, medical care, surgery, maternity, fractures, x-rays, and anesthesia was $38.55. This may not seem like very much, but when it is considered that the largest percentage of cases were for minor surgery this is not too low a figure.

In the last six months only fifty-eight non-participating doctors of medicine have received allowances for services rendered Blue Shield subscribers. This would indicate that the greater percentage of the physicians in Minnesota are now participating with Blue Shield.

Blue Shield enrollment of subscribers is progressing very well. In the month of July, the Blue Shield—Blue Cross representatives brought in almost 4,500 new applications. That, to date, is the largest number obtained in any one month. Also Blue Shield is now available to all Blue Cross subscribers who are on a bill-direct basis. There have been many requests for this type of coverage, and it is felt that now is the proper time to start it off. This will net the Blue Shield many more subscribers.

Physicians are pleased with the small amount of bookwork involved in Blue Shield cases and with the simplicity of Blue Shield forms which merely request that the diagnosis and type of service rendered be given and that the form be completed by the doctor's signature. Blue Shield, as it is growing, needs the help and cooperation of every doctor in the state, and, without a doubt, is receiving it.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

ESSENTIALS OF PATHOLOGY. Third Edition. Lawrence W. Smith, M.D., F.A.C.P. Formerly Professor of Pathology, Temple University School of Medicine; Associate Professor of Pathology, Cornell University Medical School and Assistant Professor of Pathology, Harvard Medical College; Corresponding Member of the Royal Flemish Medical Academy of Belgium; and Edwin S. Gault, M.D., F.A.C.P., Associate Professor of Pathology and Bacteriology, Temple University School of Medicine. Foreword by the late James Ewing, M.D. 764 pages. Illus. Price $12.00, cloth. Philadelphia: The Blakiston Company, 1948.

PREOPERATIVE AND POSTOPERATIVE CARE OF SURGICAL PATIENTS. Hugh C. Ilgenfritz, A.B., M.D., F.A.C.S. Formerly Assistant Professor of Surgery, Louisiana State University School of Medicine, and Visiting Surgeon, Charity Hospital of Louisiana at New Orleans. 898 pages. Illus. Price $10.00, cloth. St. Louis: C. V. Mosby Co., 1948.

HANDBOOK OF ORTHOPAEDIC SURGERY. Third edition. Alfred Rives Shands, Jr., B.A., M.D. Medical Director of the Alfred I. duPont Institute of the deNemours Foundation, Wilmington, Delaware; Visiting Professor of Orthopaedic Surgery, University of Pennsylvania School of Medicine, Philadelphia, in collaboration with Richard Beverly Raney, B.A., M.D., Associate in Orthopaedic Surgery, Duke University School of Medicine, Durham, N. C.; Lecturer in Orthopaedic Surgery, University of North Carolina School of Medicine, Chapel Hill, N. C. 574 pages. Illus. Price $6.00, cloth. St. Louis: C. V. Mosby Co., 1948.

MICROBIOLOGY AND PATHOLOGY. Fourth Edition. Charles F. Carter, B.S., M.D. Instructor in Pathology and Applied Microbiology, Parkland Hospital School of Nursing, Dallas, Texas; Director Carter's Clinical Laboratory, Dallas; Consulting Pathologist, St. Louis Southwestern Railway Hospital, Texarkana, Arkansas; Consulting Pathologist Mother Frances Hospital, Tyler, Texas; Formerly Director of Laboratories, Parkland Hospital. 845 pages. Illus. Price $5.00, cloth. St. Louis: C. V. Mosby Co., 1948.

MEDICAL WRITING, The Technic and Art. Second Edition. Morris Fishbein, M.D., Editor, The Journal of the American Medical Association. With the assistance of Jewel F. Whelan, Assistant to the Editor. 292 pages. Illus. Price $4.00, cloth. Philadelphia: The Blakiston Co., 1948.

Though Dr. Fishbein's latest book may not teach all physicians how to write perfect scientific papers, its suggestions will help any medical writer to produce a manuscript that has a better chance of being published and a far better chance of being carefully read.

Too many articles submitted to medical journals, the book points out, are merely typed copies of papers that were presented before medical societies. They were good for opening a discussion or for filling an entire evening's program. For publication, however, they need a thorough revision. Often they are verbose, ungrammatical, poorly organized and full of nonessential material. They usually are returned to the author with a polite note. Unfortunately, however, since medical journals have pages to fill and enough good papers are sometimes lacking, such manuscripts seem to appear in print fairly frequently. They are read infrequently.

An attempt to change this situation—to show writers how to prepare better papers—is made by Dr. Fishbein in this book.

Throughout the book, Dr. Fishbein makes good use of the teaching technique of indicating what *not* to do. He illustrates his points with sentences, paragraphs and photographic material taken from manuscripts submitted to the *Journal of the AMA*. He offers general rules and analyzes specific details. He states that case reports should not be jerky telegraphic transcripts from original record sheets, and that they should not contain unimportant and irrelevant observations. Medical jargon should not be used; there is no such thing as an "acute abdomen" or a "right heart." Ordinary nouns should not be made into verbs, as is often done in medical writing: "Astronomers never telescope the sky; bacteriologists never microscope their slides; but urologists do not hesitate to cystoscope their patients."

In addition to describing what the potential author should not do, Dr. Fishbein gives sound advice on how to prepare a manuscript and how to revise it; how to select and prepare illustrations, tables and charts; how to use abbreviations, arrange bibliographic material, compile an index; and how to correct proofs so that both author and printer know what is meant.

The style advocated by Dr. Fishbein for spelling, capitalization, punctuation, et cetera, is that used by the American Medical Association Press. Other editors and publishing houses may prefer different styles. Yet, a medical writer, no matter to what publication he plans to submit his paper, could do worse than to follow the AMA style described in this book. It is clear, simple and consistent, and any desired variations in it could be made easily by the copy editors of individual publications.

All in all, practically every medical writer can learn something from this book. A thorough reading of it and an observance of its suggestions should enable any scientific writer to improve his future manuscripts, and, as a result, allow medical editors to lead far more enjoyable lives.

Medicus * — writing in the Minneapolis Star of July 8 — says,

"The hospitals and their staffs are much to blame for the present shortage of applicants for nurses' training.

"Many nursing schools require that an applicant have a college degree before becoming even a probationer in a hospital. Thousands of qualified young women are thus shut off from carrying out a lifetime ambition."

GLENWOOD HILLS HOSPITALS PIONEERED in the other direction. For some years we have offered a one-year course in **modern methods, modern nursing, modern patient care** to **young women with high school education.**

They are capable of appreciating the needs of that important person the patient, giving him the right attention and the right food to make him comfortable.

Thanks to you registered physicians, our midsummer class was oversubscribed. We are now enrolling for the September class in the

SCHOOL OF PSYCHIATRIC NURSING

Our graduates are the ones most desired by doctors and clinics. . . . They are well trained, loyal, eager to serve.

Doctors who operate their own hospitals in smaller communities seek our graduates.

The most capable of these graduates are the ones who come doctor-recommended.

We appreciate the cooperation rendered by you doctors

**Medicus is the pen name of a prominent Minnesota physician.*

Nominate some young woman for the course.
We will send you and her our booklet.

Glenwood Hills Hospitals, Minneapolis 12, Minn.

BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri-Maltose.

The prevalence of "hidden rickets" in older children, confirmed by roentgenologic studies, demands that the old practice of discontinuing vitamin D administration after two or three years of age be reevaluated. Even though the effect of subclinical rickets on the health and development of the older *well child* may not be apparent, it is not unlikely that the *sick child* will be hampered by a deficit of vitamin D. "Our studies as a whole afford reason to prolong administration of vitamin D . . . and especially indicate the necessity to suspect and to take the necessary measures to guard against rickets in sick children."[1]

VITAMINS

Parke-Davis

Parke-Davis first made a preparation of vitamin D available in 1929. In the many years since then it has continued to pioneer in the discovery, standardization and development of quality vitamins for professional use. Today, twenty years later Parke-Davis has available many prescription forms of the antirachitic vitamin either alone or combined with other vitamins to meet the need of infants, children and adolescents.

Throughout the formative years . . .

From birth to at least the age of 14 years, investigators now agree children are susceptible to rickets, with scarcely diminished frequency.[1]

The critical periods of active skeletal growth are found in infancy and childhood, lasting through at least the years just preceding puberty.[2]

Throughout these formative years patient cooperation assuring an adequate vitamin D intake is readily obtained by the use of

DRISDOL® in propylene glycol

milk diffusible vitamin D preparation

Protein Nutrition *in later years*

IN later years energy requirements are about 20% lower than in the prime of life. Because of this, a reduced food intake has definite benefit. All available evidence indicates that longevity is associated with body weight under the average of the population.

From a nutritional standpoint the optimum feeding regime for the aged should be a *calorically restricted* diet, which maintains *proteins at a good level.* A high-protein, low calorie diet helps prevent fat from becoming a burden to the vital functions of the aging body, and tends to maintain cell machinery in a good state of repair.*

Swift's Strained Meats
. . . when age presents problems
in protein supplementation

When age, disease or any injurious stimuli cause problems in protein supplementation, many physicians now prescribe Swift's Strained Meats. An excellent, palatable source of complete, high-quality proteins, Swift's Strained Meats provide *all* the essential amino acids *simultaneously*—for optimum protein synthesis. Swift's Strained Meats supply goodly amounts of natural B vitamins, iron and trace minerals and are low in fat content.

Originally developed for infant feeding, these meats are strained fine—may easily be used in tube-feeding, or for oral feeding in soft diets. Since salt content of the meats is at a minimum for infants, additional salting is suggested for adult usage. Convenient—ready to heat and serve. Six kinds of Swift's Strained Meats: beef, lamb, pork, veal, liver and heart, provide variety and tempting meat flavors that help combat anorexia. 3½ ounces per tin.

Safe for injection

The safety record of NEO-IOPAX* — Schering's brand of sodium iodomethamate for intravenous urography — is noteworthy: more than fifteen years of effective urinary tract visualization *without a single fatality* reported in the literature. The relative safety of

NEO-IOPAX®

(*disodium N-methyl-3,5-diiodo-chelidamate*)

is due to its unique composition and stability, the meticulous care exercised in its preparation, the careful control of all manufacturing stages, and the rigorous inspection of the finished product. Each ampul of NEO-IOPAX is sterile and free from foreign particles.

NEO-IOPAX is available in 10, 20 and 30 cc. ampuls of 50% concentration and 10 and 20 cc. ampuls of 75% concentration. Packaged in boxes of 1, 5 and 20 ampuls.

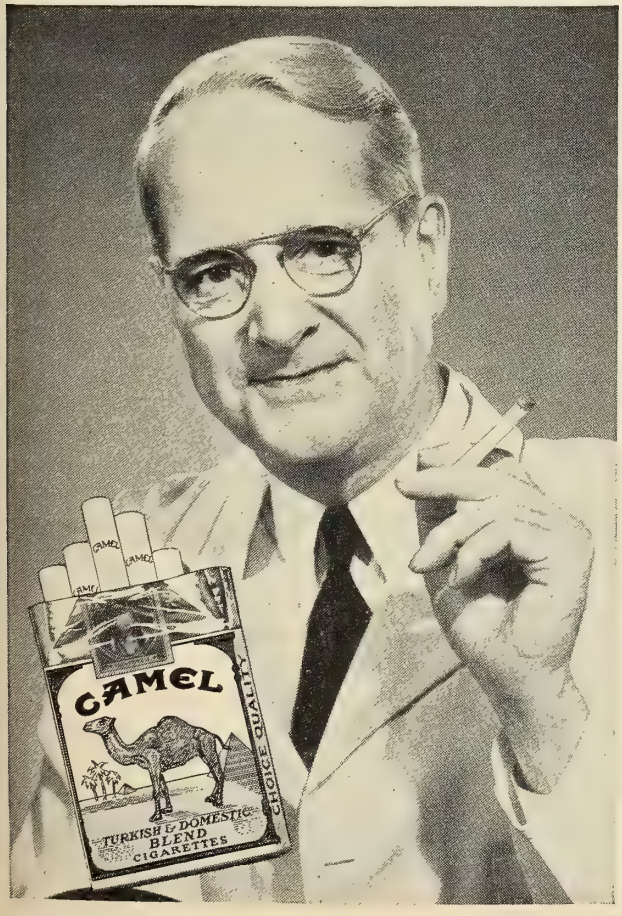
EXPERIENCE IS THE BEST TEACHER...



Carlos Finlay (1833-1915)

proved it in public health

Carlos Finlay, of Cuba, a bacteriologist, believed that yellow fever was transmitted by the stegomyia mosquito. His original experiments did not provide definite proof of his theory. However, he continued his search in co-operation with Walter Reed and the Yellow Fever Commission. The work of the Commission finally proved that infected mosquitoes could transmit the fever. The public health preventive measures derived from these experiments were so successful that the fever in Cuba was under control within a year.

R. J. Reynolds Tobacco Company, Winston-Salem, N. C.

Experience is the best teacher in cigarettes, too!

MILLIONS of smokers who have tried and compared many different brands of cigarettes have found that cool, mild, flavorful Camels suit them best

Try Camels on your "T-Zone"—T for Taste, T for Throat. See how your taste enjoys the rich, full flavor of Camel's choice, properly aged, and expertly blended tobaccos. See if your throat doesn't welcome Camel's cool, cool mildness.

Yes! Try Camels and see for yourself why, with thousands and thousands of smokers, Camels are the "choice of experience."

• • •

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS

than any other cigarette

Three independent research organizations in a nationwide survey asked 113,597 doctors to name the cigarette they smoked. More doctors named Camel than any other brand.

CAMP

ANATOMICAL SUPPORTS for NEPHROPTOSIS

Together with treatment for any existing infection of the urinary tract, Camp Supports have proven valuable adjuncts in the relief of symptoms in many cases.

Camp-trained fitters have been instructed to consult the physician as to the position required for the fitting, if reclining or partial Trendelenburg. In the event that the physician desires the use of a pad, the fitter has been instructed to obtain information as to the type of pad to be used and to ask the doctor to mark on the garment or blue pencil upon the patient the exact location of the pad.

Advantages of Camp Supports in Conditions of Nephroptosis:

1. The "lifting" power of Camp Supports is from below upward and backward.
2. Camp Supports are an aid in improving the faulty posture that sometimes accompanies renal mobility.
3. Camp Supports are easily and quickly adjusted.
4. Camp Supports stay down on the body by reason of the foundation laid about the pelvis.
5. Camp Supports are comfortable.
6. Camp Supports are economically priced.

Camp fitters ask patients to return to their physicians for approval of the fitting.

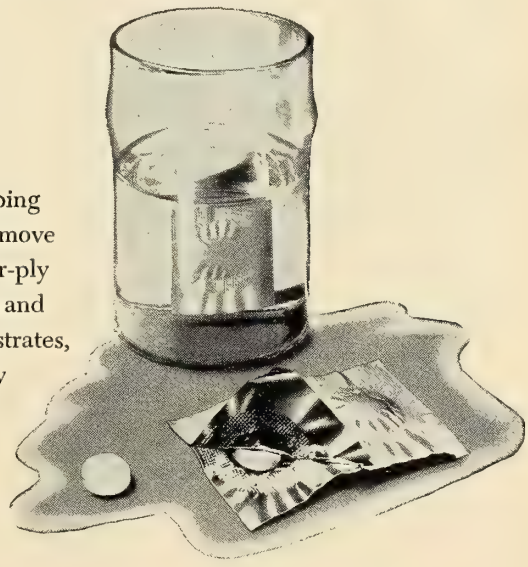
ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

Oral Penicillin

"even in serious infections . . ."[1]

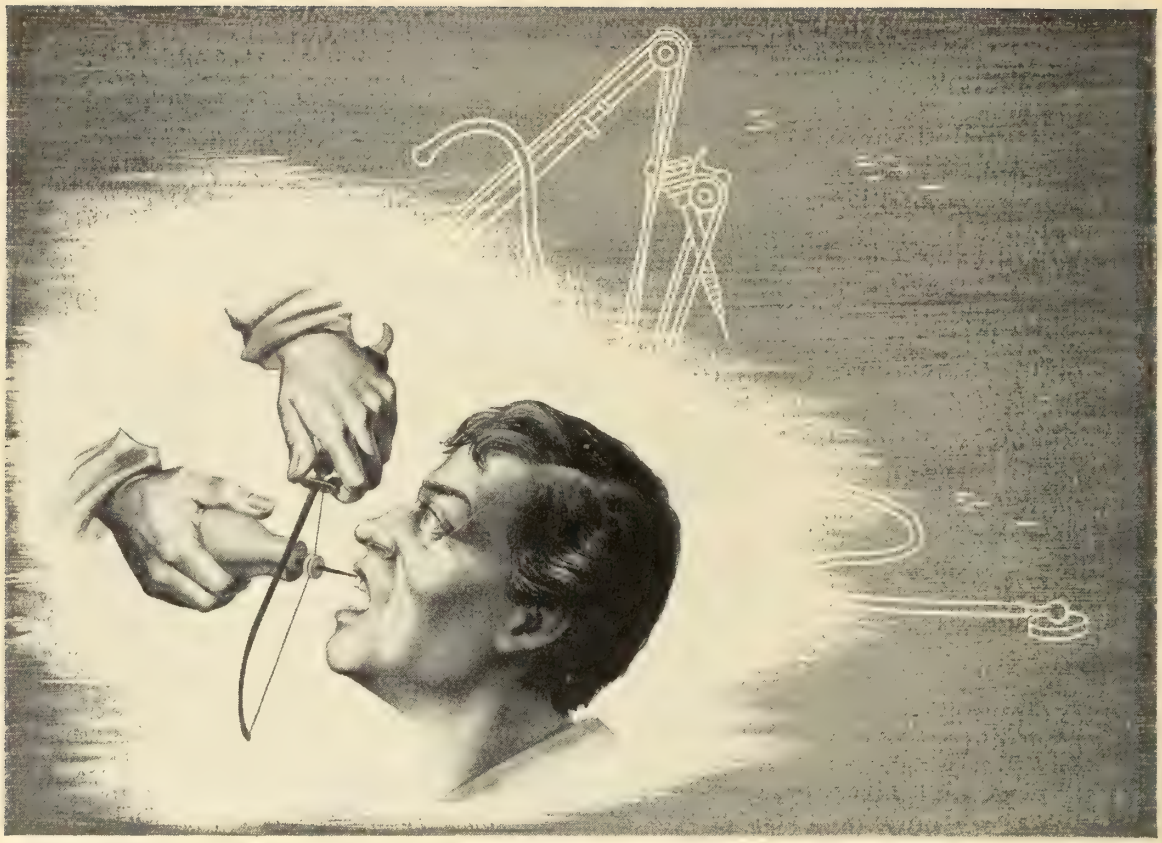


Used alone — not merely as adjuvant therapy — "orally administered penicillin is therapeutically successful even in serious infections, if a sufficiently high dose is given."[1]

By giving oral penicillin in doses of 100,000 units every 3 hours (often preceded by an initial "booster" dose of 200,000 units), clinicians have successfully treated pneumococcic lobar pneumonia, gonorrhea, and other infections, both acute and serious. Oral administration in high dosage produces penicillin serum concentrations within the antibacterial range of most susceptible pathogens. If prompt response is not obtained, parenteral treatment should be instituted immediately.

SQUIBB PENICILLIN TABLETS contain potent penicillin G for direct, active oral therapy. They are buffered for optimal absorption and are individually and hermetically sealed in a four-ply wrapping of cellulose acetate, pigment, aluminum foil and vinyl plastic to maintain full potency until administration. Tablets of 50,000 and 100,000 units, boxes of 12 and 100.

POTENCY SAFEGUARDED



Drop a Squibb Penicillin Tablet, wrapping and all, in a glass of water. When you remove it, and have wiped and taken off the four-ply wrapping, you will find the tablet whole and perfectly dry. As this simple test demonstrates, Squibb Penicillin Tablets are thoroughly sealed against penicillin-destroying moisture right up to the time of use.

SQUIBB

CRYSTALLINE PENICILLIN G SODIUM (Buffered) TABLETS

The First Modern Dentistry...

Dentistry, in the story of its evolution from "tooth tinkering" to modern methods, cites the jeweler's "fiddle-bow" drill as the first of America's mechanical devices for the preparation of cavities.

This and later nineteenth century technical developments—Lewis' hand drill with adjustable head, the finger thimble and hand bur, the first modern dental chair, the advent of sponge or crystal gold for fillings, improvements in the manufacture of porcelain teeth, etc.—were paralleled by developments in the educational field:

In 1826 Leonard Koecker's scholarly *Principles of Dental Surgery* presaged the demise of practicing laymen—a prophecy that ripened with the founding of the first dental college at Baltimore in 1840. Chapin A. Harris' *American Journal of Dental Science*, published in 1849, heralded the coming of other early educational and fraternal magazines, some of which still serve the profession today.

FOR SALE BY SURGICAL DEALERS AND DRUGGISTS

The sooner the treatment of adrenal cortical insufficiency is initiated, the shorter may be the period of convalescence and the milder the patient's disabilities.

And the closer the therapy comes to replacing the multiple action of the whole cortical hormone, the more effective it can be.

Therein lies the therapeutic excellence of ADRENAL CORTEX EXTRACT (UPJOHN)—it is a specially extracted preparation from the whole gland containing the multiple active principles of the cortex. Whenever such typical symptoms of cortical insufficiency as lassitude, lowered muscular tone, markedly reduced resistance to infections, loss of weight, depression and mental apathy call for hormone replacement, ADRENAL CORTEX EXTRACT (UPJOHN) conveys in fullest possible measure the requisite cortical principles.

WHEN *Anorexia* POSES SPECIAL PROBLEMS

Periods of anorexia following infectious disease and surgery can readily produce a series of consequences detrimental to the patient: (a) curtailed food consumption, (b) further deterioration of the nutritional state, and (c) impeded recovery.

When anorexia occurs, activation of food interest becomes a first consideration for rapid convalescence. Highly nutritious food which is at the same time tasteful, stimulative to the appetite, and easily digestible, thus possesses both a dietary and a therapeutic worth.

In convalescence when appetite lags, the delightfully tasteful food drink made from Ovaltine and milk has particular usefulness for inciting food interest. It gives the patient a threefold combination of important dietary values: worth-while amounts of virtually all essential nutrients, easy digestibility, and appetizing tastefulness. Three glassfuls of Ovaltine daily can convert even a dietetically poor to fair food intake to full nutritional adequacy.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

Ovaltine

THE CLINICAL USE OF SODIUM FLUORESCEIN AND RADIOACTIVE DIIODOFLUORESCEIN IN THE LOCALIZATION OF TUMORS OF THE CENTRAL NERVOUS SYSTEM

GEORGE E. MOORE, M.D., WILLIAM T. PEYTON, M.D., SAMUEL W. HUNTER, M.D., and LYLE FRENCH, M.D.
Minneapolis, Minnesota

FLUORESCEIN (resorcinolphthalein), a non-toxic acid chromogen dye, was injected intravenously in animals by Erlich[4] in 1882 to study the formation of fluid in the anterior chamber of the eye. In 1912, Kafka[10] injected sodium fluorescein subcutaneously in animals and found that it did not stain the brain or spinal cord but did stain all other tissues including the dura and choroid plexus. Schonfeld,[20] in 1925, also investigated the appearance of sodium fluorescein in the spinal fluid and found that when large doses (6 to 8 grams) are given by mouth, it passes in small quantity into the spinal fluid in some normal individuals but more often in patients with syphilis. Subsequently, Jervell[9] and Bonar and Bailey,[1] have suggested that the appearance of sodium fluorescein in the spinal fluid be used in the diagnosis of meningitis.

That the luminescent property of intravenous fluorescein can be observed on the body surface when examined under ultraviolet light was demonstrated by Lange and Wollheim.[11] Since 1942 a number of reports have appeared in the literature concerning the use of intravenous fluorescein to measure circulation time (arm to tongue) and to evaluate the adequacy of the circulation in an extremity.[5,12,13,19,20,21]

Moore and Campbell,[14] at the University of Minnesota, modified the test for evaluation of peripheral vascular disorders of the extremities by injecting the dye into the artery of the extremity to be tested.

Intravenous sodium fluorescein has also been used to determine the patency of circulation to strangulated viscera.[12,15]

Beginning in October, 1946, Moore[16] began intravenous injection of 5 c.c. of sodium fluorescein in patients operated upon for carcinoma of the stomach, with the thought that the tumor tissue might be differentially stained. At first, the dye was injected when the abdomen had been opened, and no difference in fluorescence of the tumor and surrounding tissues under a Woods lamp was noted. However, as the interval between the time of the intravenous injection of dye and exposure and examination of the tumor was increased, it was found that there was, at times, a good differential fluorescence. The optimum interval between injection and inspection under ultraviolet light appeared to be approximately three hours. However, many of these tumors of the gastrointestinal tract, as well as those of the breast or others parts of the body, did not retain the dye in increased amount. But when sodium fluorescein was injected intravenously in patients with tumors of the central nervous system, they almost invariably showed differential fluorescence when exposed under a Woods light approximately three hours later.[16]

This technique has been quite helpful in locat-

Dr. Moore is Senior Research Fellow, United States Public Health Service, Department of Surgery, University of Minnesota Medical School.

ing subcortical brain tumors. In this clinic, it is the custom to avoid large openings in the dura when there is increased intracranial pressure, but after the tumor has been localized, a small opening is made directly over it, and all the tumor or a sufficient part of it is removed to release the dural tension. Then, if necessary, a more adequate opening in the dura is made. After making small openings for a brain needle at the suspected site, the needle is introduced and, with syringe, suction biopsies are obtained. These are examined under a Woods light in the operating room itself, and if they fluoresce it is immediately known that the tumor has been located.

It has been found convenient to have the room nurse hold the biopsy material under the Woods lamp so that the surgeon can examine the tissue and confirm the presence or absence of fluorescence without moving from his operating position. A faint fluorescence may be obtained from the edematous tissue in the immediate vicinity of the tumor but once this area is located it is not difficult by additional needle biopsies to determine the site of maximum fluorescence, which is found in the tumor. This procedure avoids the delay of waiting for microscopic sections where the needle biopsy cannot be grossly recognized as tumor; it checks all parts of the needle biopsy for tumor and thus enables the pathologist to make sections of only the more suggestive parts; and, finally, it may give a clue to the fact that one is in the vicinity of the tumor. This procedure has now been used in sixty-five cases, and in every case but one where the biopsy did fluoresce a tumor was proven to be present by microscopic examination. An absence of fluorescence is equally consistent.[17] Here also there was one case, an angiomatous meningioma, which did not fluoresce until it was washed free of blood.

The residual cavity remaining after the tumor has been removed can be inspected for tumor tissue by noting any unusually fluorescent areas. In several instances, infiltrating portions of tumor have been discovered by examination with the ultra violet lamp and subsequently removed, thus resulting in a more complete operation. Fluorescence does not differentiate the type of tumor, but in general more malignant lesions fluoresce most highly. In our experience, every kind of intracranial tumor exposed since we have used this method has shown fluorescence enough to distinguish the tumor from the surrounding brain tissue.

The reason for this differential fluorescence is not clear. That it is not due to greater vascularity is obvious from the fact that the maximum differential does not appear until some three hours after injection. That it is not entirely a disturbance in the so-called blood-brain-barrier would appear from the fact that some gastrointestinal and other tumors also show a similar differentiation. However, its consistency in tumors of the brain and spinal cord in contrast to its inconsistency elsewhere would suggest that the blood-brain-barrier was a most important factor.

Since the experiments of Goldmann,[8] many facts about the blood-brain-barrier have been discovered. Friedman and co-workers[6,7] have demonstrated that, as a rule, substances that are blocked by the barrier carry negative electrical charges. This is true for both dyes and toxins. Broman[2,3] appears to have demonstrated the barrier to be within the blood vessels (intima), because when he injected dye and then quickly washed it out, he found the vessels of the brain unstained, but elsewhere in the body they were stained. He also found the blood-brain-barrier more easily made permeable when noxious substances were applied to the intima by carotid injection than when applied from without by application of the injurious substance to the pia.

To what degree this differential staining of brain tumors after injection of sodium fluorescein is dependent upon a disturbance of the blood-brain-barrier by tumor will have to be determined by future investigation. We have not verified by biopsy any vascular lesion in man after injection of dye. Some experiments with vascular lesions and abscesses in animals are now in progress. One tuberculous granuloma of meninges exposed at operation did not fluoresce.

Since we have begun to use vital staining in brain surgery, reports by Sorsby et al[22] have come to our attention. They made a similar attempt to differentiate tumor tissues at operation by vital staining. They used Kiton green in a few cases, but with little success.

Since sodium fluorescein was so consistently taken up by tumors of the central nervous system, it seemed possible that by combining it with one of the heavier elements, or tagging it with a radioactive isotope, its clinical usefulness might be

extended as radio-opaque or radioactive substance.[18]

Diiodofluorescein and also tetraiodofluorescein were prepared and injected, but the differential opacity within brain tumors has not been sufficient to visualize tumors in roentgenograms.

Also, radioactive diiodofluorescein was prepared with iodine$_{131}$. Iodine$_{131}$ has the requisites of relatively rapid decay (half life eight days), and it has a penetrating gamma radiation which can be readily detected at a distance.

Approximately 1 mc. of iodine$_{131}$ is injected intravenously in the form of diiodofluorescein and two to four hours later counts are made over the head with a Geiger-Mueller counter. Differential staining with fluorescein was found to be best some two hours or more after injection of the dye, so also the counting rates do not reveal significant differences until a similar period has elapsed after injection of the dye.

Counts for two- to five-minute intervals are taken over various symmetrical areas of the skull, and the counting rates per minute for each area are compared for localization of the lesion.

The results obtained on twenty-six patients who were suspected of harboring brain tumors are available for evaluation of the procedure. Only those patients in whom a lesion was later demonstrated to be present or proven to be absent by operation, ventriculogram or angiogram are included.

Summary of the above twenty-six cases: eight tumors were correctly localized; two tumors were located close to but not exactly at the correct site; in six no focal lesions could be located and none was demonstrated by operation, ventriculogram or angiogram; seven tumors were incorrectly localized or missed; one tumor was localized only as to the proper hemisphere.

It is notable that three of the eight cases incorrectly located by Geiger counts were tumors of the posterior fossa where it would appear that the procedure is less accurate because there is a greater mass of tissue between the brain and Geiger-Mueller tube. This increases the distance and interposes tissue relatively high in radioactive iodine.

In nine cases another 0.1 mc. radioactive fluorescein was injected just before operation. During operation normal brain tissue and brain tumor tissue were removed, and beta ray counts were made from the surface of a piece of each equal in surface area and more than 3 mm. thick. These counts showed the tumor to contain from approximately two to twenty-nine times as much radiation as the brain tissue. But they probably are not as significant as they might be if it were always possible to obtain entirely satisfactory specimens for comparison. However, this has not been feasible. In some cases, at least, the brain tissue has been traumatized or deprived of its blood supply (which we have reason to believe causes it immediately to take up the dye). In some cases, a considerable time elapsed between the taking of the normal brain biopsy and the exposure of the tumor and removal of a portion of it for the test. Finally, the time interval after the injection of the dye to the taking of the specimens for estimation of radioactivity was not always best for maximal differentiation.

Discussion

The use of sodium fluorescein as an aid in the localization and diagnosis of brain tumors at operation is a simple and accurate technique. The method utilizes no special apparatus except a mercury vapor lamp, which can be obtained from one of several commercial concerns. It therefore can be carried out at any hospital in which neurosurgery is done.

The use of radiopaque dyes to outline tumors of the central nervous system has not been successful. However, calculations based upon phantom experiments indicate the feasibility of the method, if the proper dyes can be synthesized.

The clinical value of the use of radioactive dyes to detect brain tumors preoperatively is yet to be determined. Some of the limitations of the method are already known. "Benign" tumors, such as acoustic neuroma, fibrous meningiomas, and certain astrocytomas, do not take up enough dye to give a differential ratio of radiation large enough to be detected by the Geiger-Mueller counter. There is also a limit as to the size of tumor that can be detected. Tumors with a diameter of less than 3 cm. cannot be detected unless surrounded by an appreciable area of edema. It is hoped that improvements in the physical apparatus itself will result in greater accuracy.

It should be pointed out that radioactive diiodofluorescein cannot be used for therapy. The dye is concentrated and excreted largely by the

liver, and therefore irreparable damage would be incurred by the liver before the comparatively radioresistent brain tumors received a carcinolytic dosage.

Conclusion

Differential staining which makes it possible immediately to recognize even minute particles of tumor in biopsies has proven to be very valuable in locating subcortical tumors by needle biopsy, and it can be used to identify remaining fractions of tumor, but only when these are entirely free from overlying hemorrhage.

The localization of tumors by Geiger count is still uncertain. Our experience with this method is quite small, and we have not yet come to rely upon it for operation on otherwise unlocalized tumors. Improvements in apparatus and technique should make it more reliable.

IS VET PROGRAM NUDGING US INTO SOCIAL MEDICINE?

A medical man who occasionally communicates his ideas to this department wonders if we may not be backing into socialized medicine through the government program of care for veterans. It's a touchy subject, he admits, but it is going to be increasingly difficult to keep under cover in the next few years. More than 80 per cent of the beds in veterans' hospitals in this area, our correspondent reports from personal check, are occupied by veterans whose disabilities can't be traced to their service in the armed forces.

As the law now stands, a veteran may go to a government hospital at any time for medical treatment or surgery. He is required to make a statement that he can't afford private medical care. But this requirement has become largely a matter of form, and the signer rarely is questioned as to his financial ability.

Demand for free service is so great that the veterans' medical program alone is costing the government currently some $400,000,000 a year. What it will cost when the majority of World War II vets arrive at the age when illness is to be expected can only be guessed. If we extend the same privilege to the new draftees, the total cost a decade hence could easily be in excess of two billions a year.

According to Veterans Administration figures, $5,000,000,000 has been spent on education and on-the-job training benefits since the GI bill was enacted in 1944. Another $3,000,000,000 has been paid to veterans as unemployment or self-employment allowances. Business, farm and housing loans now total $223,000,000.

Costly as this program has been, few Americans would have it otherwise. Moreover, the underlying premise all along has been that after the veteran is readjusted he will be a self-sufficient citizen, or at least as much so as the rest of us in this day and age. On the other hand, free medical service for life to millions of men who left the armed forces in good physical condition is stretching government's responsibility out of all semblance to reason. (The Round Table by W. J. Brons, *Chicago Journal of Commerce,* July 20, 1948).

MULTIPLE CARCINOMAS OF THE STOMACH AND CHOLEDOCHOLITHIASIS IN A PATIENT WITH PERNICIOUS ANEMIA

HARRY B. NEEL, M.D.
Albert Lea, Minnesota

STATISTICALLY, carcinoma of the stomach is the cause of more deaths than any other malignant disease. It is said that in the United States alone, more than 50,000 persons die annually from this cause.

The incidence of simultaneous multiple malignancies is small. In reports of large series of cases from different centers it varies from 3.34 to 4.7 per cent. Of 1,048 cases of multiple malignant lesions, reported by Warren and Gates, there were thirty-six cases of multiple carcinoma of the stomach, an incidence of 3.4 per cent. Brindley, Dockerty and Gray reported that in 1,184 cases of carcinoma of the stomach there were twenty-three (1.94 per cent) of multiple gastric carcinomas. In a recent study of eighty patients with intraoral epidermoid carcinoma, Slaughter found that 18 per cent had multiple independent primary tumors. Malignancies occurring in certain situations are more commonly multiple than those occurring in other organs. For example, Dockerty reminds us that papillary carcinoma of the ovary is bilateral in approximately 50 per cent of the cases and polypoid carcinoma of the colon presents multiple lesions in almost 40 per cent.

As previously indicated, multiple malignant lesions of the stomach are more rare. In February, 1946, Rickles reported a case with five primary cancerous lesions of the stomach, and he stated that in 1921 Owen reported a case with four primary malignancies of the stomach. In the case reported by Brindley, Dockerty and Gray there were four lesions in the stomach also.

In the case to be reported there were three distinct adenocarcinomas of the stomach. This case is of further interest in that the patient had pernicious anemia.

Case Report

A lawyer, aged sixty-one, was first seen in consultation with Dr. L. J. Kaasa on April 12, 1941. He complained of severe right upper quadrant abdominal pain associated with nausea and vomiting. He stated that about a year prior to that time he was jaundiced but had no pain. Since that time there had been several episodes of jaundice and some epigastric discomfort but no severe pain until March, 1941, when there was a severe attack of pain, a violent chill and subsequent jaundice. This pain did not radiate and was relieved by hypodermic administration of morphine sulphate. The present attack of pain was the most severe of any. The urine was colored and the patient had noticed that his skin was yellow.

Physical examination revealed a slender, tall, wiry, well-developed, well-preserved man. He was markedly jaundiced. Temperature was 99° F. The blood pressure 95 systolic and 65 diastolic. The abdomen was flat; the liver edge was palpable two fingers breadth below the costal margin, and it was tender. There was no rigidity, spasm or pronounced tenderness. Examination was otherwise essentially negative.

The patient stated that in 1930 a diagnosis of pernicious anemia was made at the Mayo Clinic. He remained at the clinic for ten weeks under treatment and since that time had taken liver irregularly. He had made it a practice to eat liver once a week, however, and when he felt that he was somewhat run down, he would report to his doctor for an injection of liver.

The family history was interesting in that the patient's mother died at the age of eighty-one years and his father died at the age of sixty-three years of Bright's disease.

After proper preparation, operation was performed. The gall bladder was found to be large, distended, subacutely inflamed and filled with stones. It was removed. The common duct was dilated to about three times its normal size, and a stone which measured 2 cm. in diameter was removed from the common duct. No other stones were found. A T-tube was placed in the common duct and the abdomen closed.

A choledochogram revealed great dilatation of the biliary tree but there was no deformity suggesting stones, and the dye entered the duodenum promptly. The patient insisted that the T-tube be removed. This was done about ten weeks following the operation, and the stab wound healed very promptly.

The patient was next seen in June, 1942. He stated that in May, 1942, he began to have some epigastric pain accompanied by nausea, vomiting, chills, fever and followed by jaundice. Since that time he had had two similar attacks.

Physical examination revealed essentially no change. The patient was markedly icteric. The heart and lungs were normal. The blood pressure was 105 systolic and 60 diastolic. There was some weakness in the upper right rectus scar and there was mild epigastric tenderness.

Laboratory examination revealed the urine to contain bile, but it was otherwise normal. The icterus

Read at the meeting of the staff of Naeve Hospital, Albert Lea, Minnesota, October 13, 1947.

index was 81. The erythrocytes numbered 3,620,000, the hemoglobin was 88 per cent (Dare), the leukocytes 37,000. The color index was 1.2. Examination of the blood smear revealed some anisocytosis and macrocytosis. Gastric analysis revealed the absence of free hydrochloric acid and a total acidity of 4 degrees.

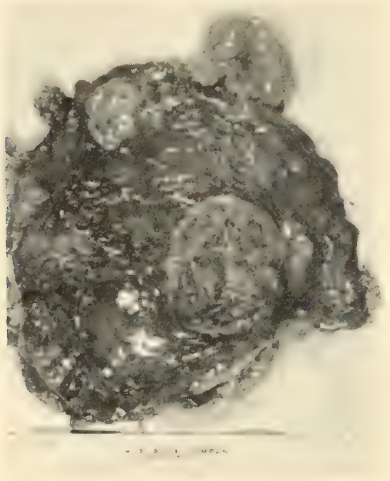

Fig. 1. Photograph of portion of stomach removed. There are three distinct adenocarcinomas.

The patient entered the hospital on August 30, 1942, after having had two more attacks of pain, nausea, vomiting, jaundice. There was no change of findings on physical examination.

Operation was performed on August 31, 1942. The abdomen was entered through the old upper right rectus scar. Exploration revealed a large carcinomatous lesion on the anterior wall of the stomach, the smaller lesion on the posterior wall of the stomach, and involvement of the glands in the gastrocolic omentum. No other evidence of extension was found. The common duct was enormously dilated so that it was at least an inch in diameter. It contained a large stone which was easily movable in the duct.

The common duct was incised and a stone measuring 2 cm. in diameter was removed. The duct was then thoroughly explored with scoops and no other stones found. A T-tube was sutured in the common duct.

The duodenum was mobilized and sectioned. The stump was inverted with two rows of sutures and buried in the head of the pancreas. About four-fifths of the stomach was removed, together with the gastrocolic omentum. A posterior Polya anastomosis was effected. Sulfanilamide powder was placed in the abdominal cavity and the wound closed in layers. The T-tube and two Penrose drains were brought out through a stab wound. A transfusion of 1,000 c.c. of whole blood was given during the operation.

The operative specimen consisted of a portion of stomach which measured 15 cm. along the lesser curvature and 24 cm. on the greater curvature. On the anterior wall there was an ulcerating lesion measuring 7 cm. in diameter, and on the posterior wall there was an ulcerating lesion measuring 3 cm. in diameter. Higher on the anterior wall there was a nodule which measured 2 cm. in diameter. One gland in the gastrocolic ligament was found to be involved. Microscopic examination of the four areas revealed them to be adenocarcinoma, Grade 4.

Convalescence was uncomplicated and the patient was dismissed from the hospital on September 20.

Choledochograms made on October 8, November 2, and December 21, 1942, revealed a dilated common bile duct but no evidence of deformity or stones. The dye entered the duodenum promptly and also made its appearance in the jejunum and in the stomach. On December 21 the T-tube was removed. The patient enjoyed good health for more than a year. During the author's absence in military service, the patient was examined elsewhere, and no evidence of metastasis or recurrence was found. During the latter part of 1943 he began to lose his appetite and began to lose weight. On January 24, 1944, he re-entered the hospital. Physical examination was essentially negative except for severe malnutrition. The urinalysis was negative. Hemoglobin was 95 per cent, and the leukocytes numbered 5,200. Occult blood was present in the stools. The patient failed gradually and died on February 23, 1944. Autopsy was not performed.

It is now generally accepted that in a large proportion of the cases of cancer of the stomach, achlorhydria is present, and that there is also a diminished volume of gastric secretion. The first communication concerning a derangement of gastric secretion associated with cancer of the stomach is attributed to Bird, who in 1842 drew attention to the lack of acid or to the small quantity of free acid in the vomitus of patients with gastric cancer. This observation stimulated further study.

Why is achlorhydria associated with cancer of the stomach? It has been suggested that the presence of the cancer interferes with the secretion, and others maintain that the carcinoma develops in a gastric mucous membrane which has been previously deranged. The evidence at hand seems to indicate that cancer of the stomach is prone to occur in those organs in which there have been chronic inflammatory changes, such as in a chronic atrophic gastritis. In pathologic studies of the gastric mucosa in stomachs affected by carcinoma, Judd, Orator, and others have found evidence of a diffuse, atrophic gastritis. To quote Rhoads, "It seems fair to assume that in certain instances gastritis is associated with cancer and, from the evidence previously discussed, that it precedes the neoplasm."

Pernicious anemia is recognized as a disease of the hematologic system characterized by pallor, weakness, anemia, macrocytosis, glossitis, and neurologic findings. The gastric mucosa is also invariably affected. According to Olson and Heck, Fenwick in 1877 first described the pathologic changes in the stomach associated with pernicious anemia. More recent studies by Brown, in the Boston City Hospital, and others, have firmly established the invariable association of gastritis with pernicious anemia.

Since gastritis is constantly associated with pernicious anemia and because of the frequent association of gastritis with carcinoma of the stomach, it seemed logical to think of gastritis as a possible etiological factor in the production of gastric cancer. Quincke first described a case of cancer of the stomach associated with pernicious anemia in 1876. Since that time many reports have appeared attesting to the high incidence of gastric neoplasm in individuals with pernicious anemia. Jenner, of Amsterdam, studied 181 cases of pernicious anemia and came to the conclusion that "there is vast difference in the incidence of carcinoma of the stomach in individuals with pernicious anemia and in the non-pernicious-anemia portion of the population." Cotti studied 107 patients with neoplasms associated with pernicious anemia and found that ninety-three (86 per cent) of the tumors were located in the stomach. Brown, in Boston, in 151 autopsies on patients dying with pernicious anemia, found that 8 per cent of the stomachs contained benign gastric tumors, neoplasms recognized as being precancerous. Schleicher, Sommers, and Ikeda have stated that about 10 per cent of their pernicious anemia patients develop carcinoma of the gastrointestinal tract. Rigler and Fink, in two large groups of cases of pernicious anemia, found the incidence of tumors of the stomach to be 7.8 per cent.

The conclusions of many clinicans, pathologists, and radiologists have been well summarized by Rigler and Fink and are as follows:

1. There is a distinct relationship between cancer of the stomach and pernicious anemia which is more than coincidental.

2. This relationship may well be on the basis of atrophic gastritis which is a predisposing factor to both diseases.

3. Carcinoma of the stomach should be suspected in patients with pernicious anemia if the slightest gastric symptoms are exhibited.

4. A routine radiographic examination of the gastro-intestinal tract of patients with pernicious anemia should be conducted semi-annually and has been found to be a fruitful procedure.

In summary, a patient with multiple carcinomas of the stomach, a rare condition, has been presented. The presence of a common duct stone was coincidental. This patient had well-established pernicious anemia of twelve years' duration.

GASTRIC CARCINOMA: ITS ETIOLOGY, SYMPTOMS AND TREATMENT

DAVID STATE, M.D.
Minneapolis, Minnesota

ONE of the penalties that we as a nation pay for an increased span of life is that more of us reach the "cancer" age. Statisticians tell us that by 1960 approximately 40 per cent of our population will be over forty-five years of age, and accordingly the annual death toll from carcinoma will be approximately 270,000.[7] In a recent article Sir Heneage Ogilvie[17] states that in England, cancer is the most frequent cause of death in men and women over the age of forty, while in this country, cancer stands next to cardiovascular disease as the chief cause of death in both males and females.

The problem of gastric cancer takes on enhanced significance in view of the above facts. Of all forms of cancer, gastric cancer is responsible for most deaths in males, and ranks second to carcinoma of the uterus as a cause of deaths in females. It is estimated that approximately 40,000 people will die from gastric carcinoma annually.[14] There can be no doubt that gastric carcinoma is a trying and grave issue that must be solved if any significant reduction in the number of "cancer deaths" is to become apparent.

Etiology of Gastric Cancer

The cause or causes of gastric cancer in man remain unknown. In pursuit of the problem of causation of gastric carcinoma, much valuable information has been uncovered. It is questionable whether gastric carcinoma ever arises on a perfectly normal gastric mucosa. Konjetzny[12] strongly maintained that chronic gastritis, particularly of the atrophic type, precedes all gastric carcinomas. However, the exact significance of gastritis, both as a clinical and pathological entity, is a sorely debated point. The careful studies of Hebbel[9] indicate that chronic gastritis occurs as commonly in people past middle life without accompanying gastric cancer, as in those with gastric malignancy.

Rigler and co-workers[11,18,20] have emphasized the frequent association of gastric carcinoma and pernicious anemia. They point out that gastric cancer is approximately ten times more frequent in patients with pernicious anemia than in the rest of the population. Magnus and Ungley[15] in this connection have described the marked atrophy of the stomach in pernicious anemia patients which, however, may disappear with adequate liver therapy. Despite the disappearance of the atrophic changes following liver therapy, some of these patients eventually develop gastric carcinoma.[8] Rodgers and Jones[21] noted the presence of superficial hemorrhagic erosions and ulcers on gastroscopic examination of patients with atrophic gastritis and idiopathic achlorhydria. These observations are of extreme importance, for the fate of these gastric erosions and ulcers should be followed carefully to see if any eventually become converted into carcinoma.

Achlorhydria and hypochlorhydria (less than 30° free acid) have long been known to accompany gastric cancer. The data of Hebbel and Gaviser[10] of our hospital reveal that 75 per cent of patients with gastric carcinoma are achlorhydric and an additional 18 per cent are hypochlorhydric after histamine stimulation. Whether achlorhydria and hypochlorhydria appear only after the gastric malignancy has developed, or whether achlorhydria and hypochlorhydria are present prior to the development of gastric carcinoma, has been answered in part by Comfort and co-workers[4] who have followed a large number of achlorhydric patients and have found that carcinoma is more likely to develop in this group than in patients who have normal gastric acidities.

Polyps of the stomach have also been indicted as precursors of gastric carcinoma by a number of authors (Borrmann,[2] Schindler,[23] Rigler and Fink[19]). Spriggs and Marxer,[24] however, after careful study of a number of patients with gastric polyp, point out that it is difficult to evaluate the actual fate of a gastric polyp in any given instance. In our clinic we have observed one patient, after a subtotal gastric resection for a benign polyp of the stomach, who returned four years later with an inoperable carcinoma arising from the residual pouch.

From the Department of Surgery, University of Minnesota Hospitals, Minneapolis, Minnesota.
The researches presented here were supported by funds from the Jane Coffin Childs Fund for Medical Research, and by the National Cancer Institute of the United States Public Health Services.
Read before the Cancer Postgraduate Clinic of the Wisconsin Division of the American Cancer Society, November 19, 1947.

The relationship between gastric ulcer and gastric carcinoma is a disputed one. That malignant transformation of a gastric ulcer may occur is denied by no one, but there is considerable debate concerning the incidence of this transformation. McCarty[16] of the Mayo Clinic reports the frequent presence of malignant degeneration in gastric ulcers—a finding which he has not observed in duodenal ulcers. Most pathologists[3] feel, however, that the incidence of malignant degeneration of a benign gastric ulcer is approximately 3 to 5 per cent. Very frequently, painstaking examination of multiple sections of an ulcer must be done before a focal area of malignancy is uncovered. The problem of mistaking a gastric carcinoma for a benign ulcer, or vice versa, is a more pressing one. Particularly so is this for ulcers occurring in the prepyloric area. Sampson and Sosman[22] have found that approximately 75 per cent of prepyloric ulcers are malignant. The roentgenologist must bear in mind the importance of his interpretations in regard to gastric ulcer and carcinoma. He should make it clearly understood that in many instances it is impossible to differentiate between the two and if his report includes "gastric carcinoma cannot be ruled out," he will do a great deal towards preventing an unnecessary delay in the treatment of the patient.

The role played by heredity in the genesis of gastric carcinoma is not well understood. Data obtained[26] from family histories of patients with carcinoma of the stomach (Tables I and II) indicate that gastric cancer occurs more frequently in relatives of patients with gastric carcinoma than in relatives of patients treated at the University Hospitals for noncancerous gall-bladder disease, carcinoma of the colon and rectum, hemorrhoids and hernia. This difference is slight and, when subjected to statistical analysis, it is not significant. If further study reveals that these small differences continue to appear consistently in the series to be studied, they may be of some significance, although it must be borne in mind that patients with cancer of the stomach are probably more likely to be aware of the same disease in other members of the family than would patients who do not have gastric carcinoma. Denk[6] has also shown that gastric cancer appears to be more frequent in the relatives of patients with gastric cancer than in relatives of individuals of similar age groups not having gastric carcinoma. Age and sex play unexplained determinant roles apparently in the genesis of gastric cancer. From 85 to 95 per cent of gastric carcinoma occurs after the age of forty. The proportion of males to females is approximately three to two.[1]

TABLE I. INCIDENCE OF CANCER IN FAMILIES OF PATIENTS WITH GASTRIC CANCER

	Number of Families	Incomplete Information	Number of Families with Carcinoma of the Stomach	Number of Families with Carcinoma Elsewhere
Carcinoma of Stomach	200	13	29 (15.6%) (36 individuals)	30 (16%) (43 individuals)
Gall-bladder Disease (noncancerous)	200	12	20 (10%) (22 individuals)	31 (16%) (39 individuals)
Carcinoma of Colon and Rectum	200	31	16 (9.4%) (19 individuals)	36 (21.3%) (64 individuals) 8% with ca. of colon
Hemorrhoids	200	13	22 (12%) (24 individuals)	33 (17.6%) (39 individuals)

TABLE II

	Number of Relatives		Number of Relatives with Carcinoma of the Stomach
	Under 45	Over 45	(% Relatives Over 45)
Carcinoma of the Stomach	888	827	16 (1.90%)
Gall-bladder Disease	318	337	3 (0.89%)
Hernia	467	281	2 (0.79%)

Diagnosis of Gastric Cancer

The usual textbook picture of severe weight loss, anorexia, hematemesis, and persistent epigastric pain depicts the late stages of the disease. It cannot be overemphasized or repeated too often, that carcinoma of the stomach in the early stages is a *silent* disease. A celebrated American radi-

ologist and two famous surgeons, who did so much to emphasize means of diagnosis and treatment of gastric malignancy, died of gastric cancer, and in each instance the diagnosis was made at a late stage by the accidental discovery of an epigastric mass. These individuals who were so well aware of the possibility of development of gastric carcinoma in others were lulled into a false state of security because they had no symptoms. Little good and, in fact, serious harm results from perpetuating the teachings that well-defined symptoms are associated with gastric carcinoma. To emphasize that the symptoms may be vague and readily overlooked in the early stages of the disease rectifies the instructions only partly. Until the fact that complete and utter lack of symptoms is characteristic of early gastric cancer is driven home to the medical profession and the "lay public," little improvement is to be expected in the end results of the present mode of therapy in cancer of the stomach.

Exactly how long gastric cancer may remain silent is not known, but from experience obtained in cases where subtotal gastric resections have been done and where malignant cells have been left in the proximal line of resection, it appears that carcinoma of the stomach is a slow-growing lesion. These patients have been free of symptoms after operation, even though viable tumor cells have been left in the residual gastric pouch, for approximately eighteen months. It is thus apparent that if *early* diagnosis of cancer of the stomach is to be made, then patients who harbor the disease and who are completely asymptomatic must be uncovered. Such a study to determine patients who might develop gastric carcinoma, or who already had it but in the early asymptomatic stage, was undertaken in this clinic in July of 1945.[26]

TABLE III. INCIDENCE OF ACHLORHYDRIA AND HYPOCHLORHYDRIA IN PATIENTS OF AGE GROUPS ELIGIBLE FOR PRECURSOR GASTRIC CANCER STUDY

No.	Gastric Expression	Achlorhydrics (Histamine)			Hypochlorhydrics
		Triple G. I. Series	Double G. I. Series	Single G. I. Series	No. G. I. Series

TABLE IV. RESULTS OF GASTROINTESTINAL SERIES IN PRECURSOR GROUPS

Precursor Groups	Number of Gastrointestinal Series	Findings	
		Polyps of Stomach	Carcinoma of Stomach
Achlorhydrics	936	29	3*
Hypochlorhydrics	34		
Pernicious Anemia	113	4	2
Relatives of patients with Gastric Cancer	43		
Patients with Occult Blood in the feces	64		
Patients with hemoglobin level of 11.0 grams or less	28		
Total	1218	33	5

*2 additional carcinomas missed through organizational errors.

The following groups were subjected to gastric roentgenograms at six-month intervals: (a) patients over the age of fifty* and free of digestive complaints, with achlorhydria and hypochlorhydria (less than 30° free acid) after histamine stimulation; (b) patients with gastric polyps; (c) patients with pernicious anemia; (d) patients with an unexplained hemoglobin level of 11.0 grams or lower; (e) patients with occult blood in the stool; and (f) relatives of patients with gastric carcinoma.

The results of this study from July 1, 1945, to October 1, 1947, are summarized in Tables III and IV.

The need for developing some workable plan for filtering off those cases most likely to harbor a gastric malignancy was additionally substantiated by the studies of St. John, Swenson, and Harvey,[27] and of Dailey and Miller.[5] The former investigators subjected 2,413 patients over the age of fifty, without gastric complaints, to a brief fluoroscopic examination of the stomach after the ingestion of barium. In this group of patients, two silent gastric cancers and one lymphosarcoma were found, an incidence of unsuspected gastric malignancy of 1.24 per thousand

*Prior to January 1, 1946, the age level for male patients was fifty-five years, and for female patients, sixty-five years.

patients. No gastric polyps were encountered by the Columbia group. Dailey and Miller reported a series of 500 patients subjected to barium examinations of the stomach. These examinations were performed on presumably normal men over the age of forty-five years, free from digestive complaints. Three gastric lesions were found: a benign gastric ulcer, a polyp, and antral gastritis in a third patient. In our study, limiting gastric roentgenograms to the above listed "precursor" groups, an effective filter has been interposed. For, of the 1218 roentgenograms in 752 individuals, five unsuspected gastric carcinomas and thirty-three gastric polyps have been found. The yield from such a study can be expected to increase with time, for it is our belief that a number of these patients who do not have gastric carcinoma at the time of the first examination may well develop this lesion, which will be found when repeat examinations at six-month intervals are done.

The results of this pilot study have been encouraging, and until some simple biological test for cancer becomes available, we feel that the regular examination at six-month intervals of apparently well individuals over the age of forty-five, such as could be accomplished at a cancer detection center, will uncover many early gastric cancers as well as early carcinomas and precancerous lesions of other organs.

Therapy of Gastric Carcinoma

The only effective mode of therapy available at present is gastric resection. If there has been any encouraging progress made in the problem of gastric carcinoma in the last twenty-five years, it has been in the field of operative attack. Through better preoperative preparation of patients, better anesthesia, adequate and timely replacement of blood loss at operation, the advent of antibiotics (particularly penicillin), and a better understanding of the postoperative fluid requirements of the patients, gastric resection is being accomplished successfully in many more patients than formerly.

At this clinic partial gastric resection is done through a left subcostal incision. Care is taken to remove the gastrocolic ligament, the greater omentum, and particularly the gastrohepatic ligament. The entire lesser curvature portion as well as the lymph nodes at the origin of the left gastric artery are excised. Wide removal of the stomach beyond the visible and palpable limits of the carcinoma is carried out, for there may be submucosal spread of a carcinoma for long distances beyond the confines of the tumor. Frozen sections and microscopic examination of the tissues of the proximal and distal lines of resection are done to determine if the surgeon is beyond the carcinoma. A 6 cm. aseptic "one-row" anastomosis between the gastric pouch and first portion of the jejunum or third portion of the duodenum, using interrupted silk sutures as described by Wangensteen,[28] is then accomplished. The ever-increasing aggressive attitude of the surgeons at this clinic has resulted in an increasing number of gastric resections with simultaneous excision of adjacent viscera (pancreas, colon, mesocolon, spleen, diaphragm, kidney, et cetera) as well as an increasing number of total gastric resections accomplished either through an abdominal or combined abdomino-thoracic approach.

TABLE V. OPERATIVE PROCEDURE AND OPERATIVE MORTALITY IN GASTRIC CARCINOMA

	Number of Patients	Per Cent of Total	Operative Mortality %
Patients with No Operations	138	23.7	
Laparotomy only	85	14.5	8.2
Palliative Procedures			
(a) Gastric Enterostomy	25	4.3	24.0
(b) Enterostomy	30	5.1	13.4
Resections			
(a) Partial	276	47.1	15.2
(b) Total	31	5.1	30.0
(c) All type	307	52.2	16.6
Total Operations	447	76.3	17.9

Recently the results of surgical therapy in gastric carcinoma at the University of Minnesota Hospitals over a ten-year period (1936 to 1945) have been reviewed.[25] The total number of patients in this group seen at the University of Minnesota Hospitals over the ten-year period was 586. Of these, 432 were men and 154 women. The average age of the patients was 63.2 years. Of this group, nineteen patients were in the terminal stages of their disease when first seen, so that surgical therapy was not feasible, but they are included for statistical purposes. Four hundred and forty-seven patients were operated upon, an operability rate of 76.3 per cent (Table V). In this group of 447 patients, eighty-five (14.5 per cent) had laparotomies only, twenty-five (4.3 per cent) had gastrojejunostomies, and thirty (5.1 per cent) had enterostomies. Three hundred and seven patients

TABLE VI. CAUSES OF DEATH FOLLOWING GASTRECTOMY (ALL TYPES)*

Peritonitis	28
Pulmonary Complication	8
Cardiac Failures	4
Renal Complications	3
Pulmonary Embolism	2
Cerebrovascular Accident	1
Shock	1
Undetermined	4
Total	51

*Forty-four autopsies obtained.

underwent gastric resection, a resectability rate of 52.2 per cent. In this group there were thirty-one total gastric resections and 276 partial resections. The resectability rate based on the total number of patients studied was 52.2 per cent, but when determined on the basis of those subjected to laparotomy (447), it was 68 per cent.

Postoperative Mortality

Among the patients with gastric resection (307) there were fifty-one deaths, a mortality rate of 16.6 per cent (Table V). There were 276 partial gastric resections with an operative mortality of 15.2 per cent and thirty-one total gastric resections with an operative mortality of 30 per cent. The gastric resections were not subdivided into simple and complicated cases for this report. However, in 65 per cent of all resected cases there were metastases to the regional lymph node and/or extension of the carcinoma to other organs, necessitating extensive surgical procedures.

Those operative procedures, which were purely palliative, carried with them a not insignificant mortality. There were eighty-five laparotomies performed with a mortality rate of 8.2 per cent, twenty-five gastrojejunostomies with a mortality rate of 24 per cent and thirty enterostomies with a mortality rate of 13.4 per cent.

Of the fifty-one deaths after gastric resection, it was possible to obtain autopsies in forty-four of these cases. The major cause of death (Table VI) was peritonitis, which accounted for twenty-eight fatalities. Eight patients succumbed to pulmonary complications (atelectasis and pneumonia); four died of cardiac failure, three of renal complications, two of pulmonary embolism, one of cerebrovascular accident, and one of shock; in four cases the cause of death was undetermined. Most cases of peritonitis appeared before 1940, when the closed method of gastric resection was not routinely used. Since the routine use of the closed method of gastric resection and anastomosis, peritonitis has been infrequent indeed after simple gastric resection. The majority of the instances of peritonitis occurred after total gastrectomy or after complicated gastric resections which necessitated simultaneous excision of adjacent organs such as liver, pancreas and the colon.

Fate of Patients Surviving Gastric Resection

It was possible to determine the fate of each of the 307 patients subjected to gastric resection.† Two hundred and fifty-six patients survived operation, but it is only those patients operated on prior to 1943 that one can speak of as "three-year cures," and only those patients operated on prior to 1942 can be considered "five-year cures." Table IV indicates the number of patients who survived for three years after gastric resection in the years of 1936 to 1943. The percentage based on the total number of patients seen (447) was 10.7, but based on the number of those subjected to gastric resection (213) the percentage of three-year survivors reaches 29.4 per cent. In all, forty-seven patients survived three years, twenty-two patients survived five years, making 6.6 per cent of all patients seen (328), but if calculated on the basis of patients surviving gastric resection (102), the percentage of five-year survivors becomes 21.5.

The operability and resectability during the ten years of study have increased steadily, while the mortality has decreased. In 1936 the operability and resectability rates were 57 per cent and 28 per cent, whereas in 1945 these rates were respectively 88 and 80 per cent. The resectability rate for 1945 based on the number of patients explored was 89.7 per cent. The mortality rate for partial gastric resection in 1936 was 25 per cent, while in 1945 it was 4.9 per cent, which figure includes both total and subtotal gastrectomy. This aggressive attitude toward gastric resection has yielded greater return, for in 1936, of fifty-eight patients, only ten (16.7 per cent) left the hospital, whereas in 1945, of seventy-eight patients, fifty-eight (82.8 per cent) left the hospital with a chance for cure or worthwhile palliation.

A critical analysis of operative procedures

†We are indebted to referring physicians and members of the Department of Vital Statistics of the Minnesota State Public Health Department who aided us greatly in our follow-up of patients.

points quite clearly to the fact that only gastric resection offers any significant periods of palliation. After gastroenterostomy the average survival was 5.4 months. With enterostomy the survival period averaged 3.5 months. When gastric resection is done, even though a cure was precluded because of the extent of the disease or metastasis to regional nodes, the patients survived on an average of 22.4 months. Even in the presence of liver metastasis (provided they were not too extensive), the average number of months of palliation averaged approximately fifteen.

TABLE VII. SURVIVAL OF PATIENTS OPERATED ON IN THE YEARS 1936 TO 1943 INCLUSIVE

Year	Total Number of Patients	Number of Gastric Resections	A			B		
			Patients Surviving 3 Years		% of Those Surviving Gastrectomy	Patients Surviving 5 Years		% of Those Surviving Gastrectomy
			No.	%		No.	%	
1936	58	16	4	7.0	40.0	1	1.7	10.0
1937	47	17	5	10.0	45.0	4	8.5	30.7

1943	67	43	9	14.0	26.0			
Total	447	213	49	10.7	29.4	22	6.6	21.5

Summary and Conclusion

1. Carcinoma of the stomach assumes an important role in the over-all problem of malignancy, for it is responsible for approximately 40,000 deaths annually. As the age of the population continues to increase, the number of patients dying from this disease will also increase.

2. Little is known about the causes of carcinoma of the stomach in man. The relationship of atrophic gastritis, pernicious anemia, achlorhydria and hypochlorhydria, gastric polyp, gastric ulcer and heredity to the genesis of gastric carcinoma has been discussed.

3. Gastric cancer in its early stages is a silent disease. Well-developed symptoms usually appear only after the carcinoma has grown extensively.

4. Gastric carcinoma is apparently a slowly growing lesion, for patients with tumor in the residual gastric pouch after partial gastric resection are usually free of symptoms for approximately eighteen months.

5. In an effort to diagnose gastric cancer in its early silent form, the following groups of individuals over the age of fifty years were studied: (1) patients with achlorhydria and hypochlorhydria (less than 30° free acid) after histamine stimulation; (2) patients with gastric polyps; (3) patients with pernicious anemia; (4) patients with unexplained hemoglobin level of 11.0 grams or lower; (5) patients with occult blood in the stool; and (6) relatives of patients with gastric carcinoma. To date, 752 patients falling into these groups have had 1218 roentgenograms with the discovery of five silent gastric carcinomas and thirty-three polyps. These findings are sufficiently encouraging, it is felt, to warrant the establishment of a cancer detection center, where the patients will be investigated for all forms of silent visceral cancer, including gastric cancer.

6. The only effective mode of therapy of gastric cancer at present is gastric resection. Details of the type of gastric resection done at this clinic are described and discussed. Over a ten-year period (1936 to 1945 inclusive) 586 patients with gastric carcinoma have been seen at the University Hospitals. Nineteen of these patients were terminal when first seen, and no therapy was possible for these individuals. Four hundred and forty-seven patients were operated upon, an operability rate of 76.3 per cent. Three hundred and seven patients underwent gastric resection, for a resectability rate of 52.2 per cent. In this group there were thirty-one total gastric resections, and 276 partial resections. The previous highest resectability rate was 44.6 per cent, reported by Lahey.[13]

7. The mortality rate for all gastric resections was 16.6 per cent. For partial resections it was 15.2 per cent and for total gastric resections it was 30 per cent.

8. The chief causes of death postoperatively were, in order of frequency, peritonitis, pulmonary complications, cardiac failure, renal com-

plications, and pulmonary embolus. In four instances, the cause of death was undertermined.

9. Because sufficient time has not elapsed, the percentage of patients surviving three and five years can only be determined in relation to those patients operated on in the periods 1936 to 1943, and 1936 to 1941 respectively. The percentage of patients surviving three years after gastrectomy was 10.7 per cent, but based on the number of patients subjected to gastric resection, it was 29.4 per cent. The percentage of patients surviving five years was 6.6 per cent, but determined on the basis of the number of patients surviving gastric resection, it was 21.5 per cent.

10. Gastric resection was the only palliative procedure of value. The average number of months of palliation following gastric resection was approximately twenty-two.

11. The operability and resectability during the ten years of study have increased steadily, while the mortality has decreased markedly. In 1936 the operability and resectability rates were 57 per cent and 28 per cent, whereas in 1945 these rates were, respectively, 88 and 80 per cent. The resectability rate was 89.7 per cent, based on the number of patients explored in 1945. The mortality rate for partial gastric resection in 1936 was 25 per cent, while in 1945 it was 4.9 per cent, which figure includes both total and subtotal gastrectomy.

FATAL ACCIDENTAL POISONING

Fewer accidental deaths have been recorded in recent years from virtually every type of poison-containing compound with the notable exception of the barbiturates, which now are far and away the leading cause of fatal accidental poisonings. In 1946 barbituric acid and its derivatives accounted for more than a quarter of all fatal accidental poisonings in the United States; in the early 1930's their share was only about 1/18 of the total. The pattern of accidental poisonings in the United States has undergone other marked changes over the years. Nux vomica and strychnine, which as recently as the late 1930's were charged with the loss of about 100 lives annually, took only 45 lives in 1946. Bichloride of mercury is another of the classical poisons that is causing fewer deaths now than formerly. Wood and denatured alcohol, which two decades ago exacted a death toll far greater than any other class of poisons, is now second in importance, taking 139 lives in 1946 as compared with 436 for the barbiturates.—*Bulletin, Metropolitan Life Insurance Company,* August, 1948.

PITFALLS IN THE EARLY DIAGNOSIS OF CARCINOMA OF THE LUNG

C. ALLEN GOOD, M.D.

Rochester, Minnesota

ACCORDING to statistics in the *Minnesota Cancer Bulletin*,[6] carcinoma of the lung causes about 6 per cent of all deaths due to malignant disease. Ten per cent of all deaths due to cancer in men are attributable to pulmonary carcinoma. Of the malignant lesions causing death in men it is the equal of cancer of the prostate and second only to cancer of the stomach. In some clinics carcinoma of the lung outranks all other forms of malignant disease as a cause of death in men.

At present the only effective therapeutic measure against carcinoma of the lung is surgical removal. Surgery offers about the same promise of cure of carcinoma of the lung as it does in carcinoma of the stomach. It is said that about a fourth of all carcinomas of the stomach can be removed when first encountered. If the lesion is removed, about a fourth of the patients live five years or more.[5] This means that six or seven of every 100 patients suffering from carcinoma of the stomach have a chance to be alive five years later. Recently Ochsner, DeBakey and Dixon reviewed their experience with resection for pulmonary carcinoma. About a third of the patients suffering from malignant disease of the lung who consulted them underwent resection. About a fourth of these survived at least five years. Their figures indicate that eight of every 100 patients suffering from carcinoma of the lung have a chance to live five years or more.

These same workers showed conclusively that the chances of survival after surgical extirpation of a bronchogenic carcinoma are much greater if the disease is localized. No patient in their series survived longer than three years after surgical extirpation if the disease had extended beyond the lung, either by encroachment on neighboring structures or by regional metastasis. On the other hand, more than half of their patients whose malignant lesions were localized lived three or more years after resection.

The results of surgical treatment of malignant disease of the lung can be improved by earlier diagnosis. Ochsner, DeBakey and Dixon concluded:

> "Every calculation, regardless of the standpoint from which it is made, indicates that while the patient's chances of survival are influenced by the type of care he receives, the important consideration is that he is seen early, so that complete removal of his lesion is possible and can be achieved without undue risk at operation. . . . The key to early diagnosis is the recollection of the possibility of the disease in all patients with symptoms referable to the chest, particularly those over forty years of age. Routine roentgenologic examination is the most valuable of all diagnostic methods. It should be supplemented as indicated by bronchography, bronchoscopy and biopsy, examination of expectorated material or of material aspirated at bronchoscopy, and, if the diagnosis cannot otherwise be arrived at, by exploratory thoracotomy."

Because so much depends on early diagnosis of carcinoma of the lung it behooves all physicians to be aware of the pitfalls which can delay early recognition of a pulmonary carcinoma. Some of these pitfalls stem from the fact that bronchogenic carcinoma can imitate the roentgenologic appearance of many benign pulmonary lesions. Because of the roentgenologic findings in cases of this type the possibility of carcinoma either is not considered or is dismissed by the consulting physician. It is the purpose of this paper to point out three of the ways in which carcinoma of the lung may masquerade as a benign lesion.

Carcinoma Simulating Benign Tumor
